EXECUTIVE SUMMARY

The purpose of this report was to evaluate baseline loadings of nutrients and sediment to the Mississippi River from the state of Illinois and to identify the sources of those loads. During the course of preparing this information, it was deemed appropriate to include similar information on the portion of Illinois which drains into the Ohio River basin. The Illinois EPA's Ambient Water Quality Monitoring Network was selected as the data set to conduct this analysis because it provided a statewide network with consistent sampling and analysis methods over an extended period of time. The network consists of 209 stations on streams ranging in size from agricultural drainage ditches to the Mississippi River. The time period for data selected was from October 1980 through September 1996. Parameter selection included nitrogen measured as total ammonia-N, total nitrate+nitrite-N and total Kjeldahl nitrogen, total and dissolved phosphorus, total suspended solids and stream flow. To determine loads and yields, total ammonia-N and total nitrate+nitrite-N were added together as inorganic nitrogen. Nitrates and total Kjeldahl nitrogen were added together to determine total nitrogen. For this report, baseline loads were determined from the mean load calculated from the samples collected over the period of record. Baseline yields were determined by dividing the baseline load by the drainage area.

The analysis began with a review of parameter concentrations to evaluate spatial and temporal variability within the state. Mean concentrations of ammonia, along with total and dissolved phosphorus, were typically highest in streams influenced by point source discharges but otherwise showed limited spatial variability. Nitrate concentrations were highest in central and eastern Illinois but were significantly lower in the streams of southern Illinois. Total suspended solids concentrations were highest in tributaries to the Illinois River in the western and lower portion of the watershed along with some of the smaller direct tributaries to the Mississippi River such as Bear Creek and Bay Creek. Significant variability in concentrations over time, both seasonally and annually, were present in all six of the chemical parameters.

The sources of baseline loadings of nutrients and sediments to the Mississippi River from Illinois followed flow volumes. The Illinois River basin accounted for 72 percent of the baseline inorganic nitrogen loading, 56 percent of the baseline phosphorus loading and 57 percent of the baseline sediment loading to the Mississippi River from Illinois. At the beginning of the Illinois River, the Kankakee River was the primary source of baseline inorganic nitrogen and suspended solids loads, while the Des Plaines River was the primary source of baseline phosphorus loads. Further downstream, the Sangamon River had the highest baseline loads of inorganic nitrogen and phosphorus. The Spoon River and Mackinaw River had the highest baseline loads of suspended solids to the Illinois River. When viewed by yields (amount per area) within the Illinois River basin, the Vermilion River had the highest baseline yields of inorganic nitrogen (43.7 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$), the Chicago Sanitary and Ship Canal the highest baseline yields of phosphorus (8.9 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$) and the Mackinaw River, the highest baseline yield of suspended solids (3,510 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$).

The Rock River basin was the second largest contributor of baseline loadings to the Mississippi River from Illinois and accounted for 19 percent of the baseline inorganic nitrogen loading, 21 percent of the baseline total phosphorus loading and 16 percent of the suspended solids loading. The Kaskaskia River was the third largest contributor of baseline inorganic nitrogen loads, 3.2 percent and total phosphorus, 10.8 percent, however, the smaller direct tributaries when combined, accounted for a larger percentage of the baseline loads than the Kaskaskia River.

Sources of baseline loadings of nutrients and sediments to the Ohio River watershed from Illinois did not follow flow volumes. Four basins, the Vermilion River, Little Vermilion River, Brouilletts Creek and Embarras River, accounted for 84 percent of the baseline inorganic nitrogen load from Illinois to the Ohio River basin via the Wabash River. This was due primarily to the high concentrations of nitrates in these streams. The Little Wabash River basin, which had the highest mean discharge of any of the Ohio River tributaries, accounted for only 12.7 percent of the inorganic nitrogen load. Unlike the other basins in the Ohio River drainage, nitrogen loads from the Little Wabash River were due primarily to organic nitrogen. Total phosphorus and total suspended solids loads from Illinois to the Ohio River basin were more evenly distributed with the Little Wabash River basin accounting for 38 percent of the phosphorus load and 26 percent of the sediment load, the Embarras River basin, contributing 29 percent of the phosphorus load and 25 percent of the sediment load and the Vermilion River basin 20 percent of the phosphorus load and 38 percent of the sediment load from Illinois.

In addition to the statewide baseline loads, an effort was made to better delineate the export of nutrient loads from Illinois on an annual basis. These loads were calculated using a regression equation from 21 stations located at the farthest downstream monitoring station within their watersheds, to estimate the export of nutrients from Illinois during the 1996 water year. A regression model with seven estimated parameters was designed for each station based on the relationship between concentration and flow. The USGS daily flow data was then used to estimate daily loads. Regression models were also developed for four border stations: two on the Mississippi River at Keokuk, Iowa and Thebes, Illinois; the Wabash River at Hutsonville, Illinois and the Ohio River at Olmstead, Illinois, for purpose of comparison.

Results of where the nutrient loads were coming from, based on the regression model, were similar to those presented in the statewide baseline section. The majority of total nitrogen loads leaving the state of Illinois into the Mississippi River basin were coming from the Illinois River basin (69.4 percent) followed by the Rock River basin (19 percent), the Kaskaskia River basin (4.6 percent) and the smaller direct tributaries (7 percent). Distributions of phosphorus loads were the Illinois River basin (56 percent), Rock River basin (19 percent), Kaskaskia River basin (13 percent) and the direct tributaries (12 percent). Loads of total and inorganic nitrogen leaving the state of Illinois into the Mississippi River basin during the 1996 water year were equivalent to 23 and 26 percent of the total load on the Mississippi River at Thebes, Illinois, respectively. Loads of phosphorus leaving Illinois during the 1996 water year were equivalent to 25 percent of the total phosphorus load on the Mississippi River at Thebes, Illinois. The export

of inorganic nitrogen, total nitrogen and phosphorus from Illinois to the Mississippi River basin, were lower during the1996 water year, than the 16 year mean. However, loads of those constituents on the Mississippi River at both Thebes, Illinois, and Keokuk, Iowa, were higher during the 1996 water year than the long term mean. These percentage assume that there is no loss of nitrogen or phosphorus due to transformation, respiration or settling out into sediments.

If nutrient loads are going to continue to receive more attention, an effort will be needed to either maintain the current level of stream gaging activities or to add additional stream gage sites. Development of regression equations to predict flows at ungaged sites will also be necessary. In addition, two monitoring efforts would go a long way toward better delineating sources of loads within the state of Illinois. The first would be to increase the number of Illinois EPA AWQMN stations where total Kjeldahl nitrogen is analyzed. For example, only three of the major tributaries to the Illinois River, the Fox River, the Sangamon River and the LaMoine River, had TKN data allowing for the calculation of total nitrogen. Second, in order to better delineate the effects of point source loadings, the Illinois EPA should collect total nitrate + nitrite nitrogen, TKN and total phosphorus in addition to total ammonia-N as part of routine effluent monitoring.

1. INTRODUCTION

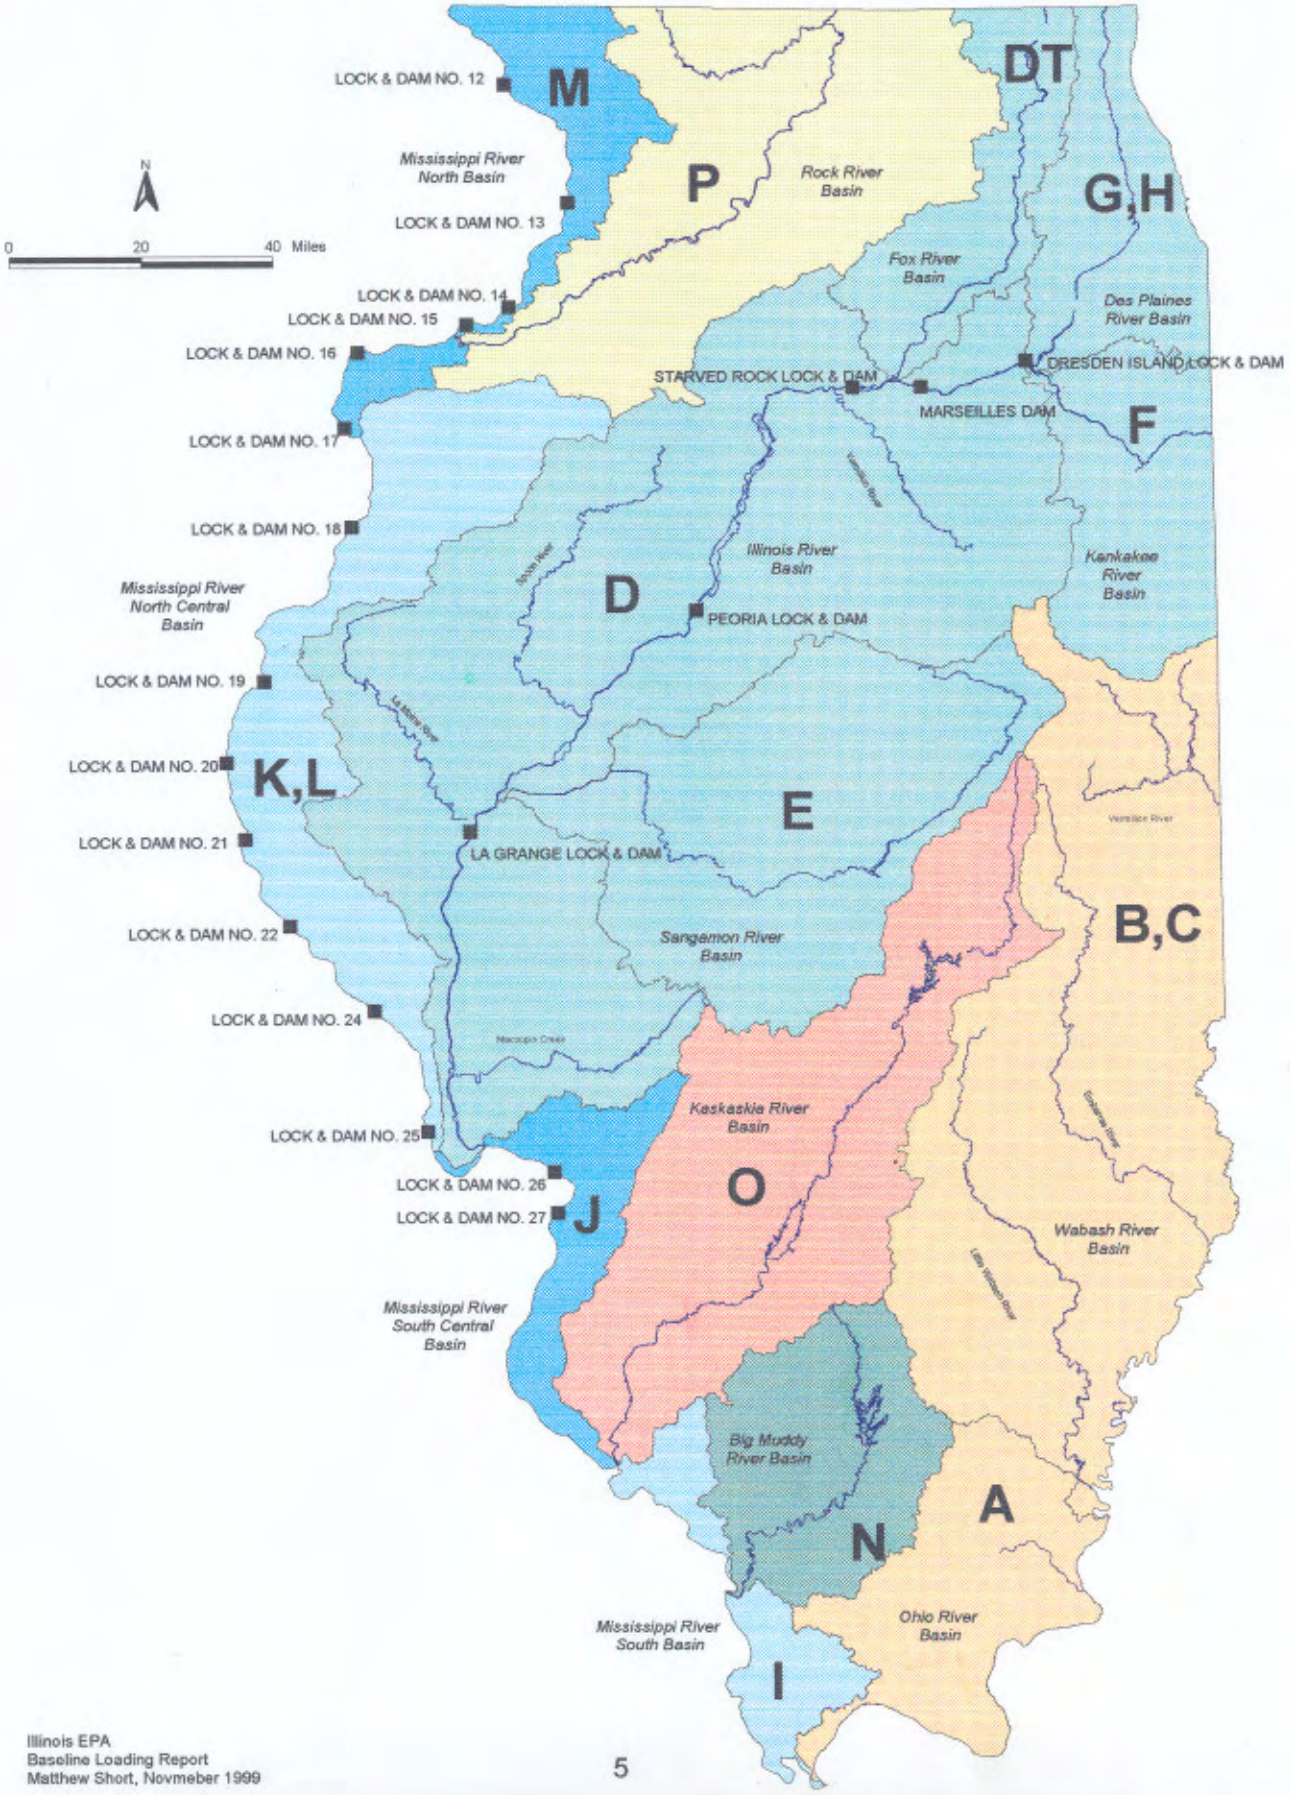
In 1998 the Illinois Environmental Protection Agency (Illinois EPA) received a grant from the United States Environmental Protection Agency (USEPA) (#82 591010) to establish baseline loadings of nutrients and sediments to the Mississippi River from the state of Illinois. This study was prompted by concerns over the 'Gulf Hypoxia' issue. The Gulf Hypoxia issue deals with a zone in the Gulf of Mexico where benthic oxygen levels are depleted. High nutrient loads from the Mississippi River have been suspected as a cause of this phenomenon. This report focuses on the parameters necessary for determining nutrient and sediment loadings from Illinois: total ammonia-N (NH_4 + NH_3); total nitrate+nitrite-N; total Kjeldahl nitrogen; total and dissolved phosphorus; total suspended solids, and stream flow. The data source for the analysis was the Illinois EPA's stream Ambient Water Quality Monitoring Network (AWQMN). For this report, baseline loadings refers to mean loadings calculated over a 16 year period of record (October 1980 through September 1996) from long term monitoring stations operated by the Illinois EPA . Baseline yields refers to mean loadings for the 16 year period of record, divided by the drainage area at the station. For purposes of loadings, nitrogen in this report is referred to as either inorganic nitrogen or total nitrogen. Inorganic nitrogen loads were based on adding the baseline load of total ammonia-N with total nitrate + nitrite-N. Total nitrogen loads were based on adding loads of total nitrate + nitrite-N with total Kjeldahl nitrogen.

Overview of Watersheds in Illinois

Illinois has approximately 55,754 square miles of surface area (Ryan, 1991). The majority of the state, 44,790 miles^2 (80.3 percent), drains to the Mississippi River (Figure 1-1). The Mississippi River comprises the entire western border of Illinois, and consists of 580.5 navigable miles. River miles on the Mississippi River are measured along the main channel and begin with mile 0.0 at the confluence with the Ohio River at the southern tip of Illinois. The Illinois portion of the Mississippi River contains a series of 15 locks and dams numbered 12 through 27 (there is no number 23) to allow commercial navigation on the river. Dam 27 is located on the Mississippi River below the confluence with the Missouri River at the beginning of the Chain of Rocks Canal. The lock works (27) are located at the downstream end of the canal. The United States Army Corps of Engineers maintains the locks and dams along with a nine foot navigation channel on the Mississippi River. Three major tributaries flow from the state of Illinois into the Mississippi River including, from north to south, the Rock River, the Illinois River and the Kaskaskia River. There are also numerous smaller tributaries. Most of the general watershed information presented here, such as historical flows, stream lengths and drainage areas, was based on data found in publications by the United States Geological Survey (Healy, 1979 and Wicker et al., 1997).

The Rock River is located in northwestern Illinois and stretches 162.8 miles from its mouth near the city of Rock Island, at Mississippi River mile 479.1, to the Illinois-Wisconsin

Figure 1-1. Illinois EPA major river basin code delineations.



Illinois EPA
Baseline Loading Report
Matthew Short, Novmeber 1999

border. The Rock River drains a total of 10,915 mi^2 in Illinois and Wisconsin. The Illinois portion of the Rock River drainage consists of 7,452 mi^2 : 68.27 percent of the total Rock River basin, or 13.4 percent of the total surface area of Illinois. There are 19 AWQMN stations in this watershed including five stations on the Rock River. Major tributaries to the Rock River include the Green River, Pecatonica River and Kishwaukee River.

The Illinois River stretches 273 miles from its mouth at Mississippi River mile 217.5 near Grafton, Illinois, to the confluence of the Des Plaines River and Kankakee River which form the Illinois River. The Illinois River drains a total of 28,906 mi^2 in Illinois, Indiana and Wisconsin. The Illinois portion of the drainage consists of 26,879 mi^2 or 93 percent of the total watershed. The remaining 1,920 mi^2 are located primarily in Indiana with 113 mi^2 located in Wisconsin. The Illinois River forms the largest drainage within the state of Illinois, covering 48.2percent of the surface area. A series of seven locks and dams have been constructed to control water levels on the Illinois River and Des Plaines River to allow for commercial navigation. Major tributaries to the Illinois River (from upstream to downstream) include the Fox River, Vermilion River, Mackinaw River, Sangamon River, Spoon River and LaMoine River. There are 94 AWQMN stations in the Illinois River watershed including eight on the Illinois River.

The Kaskaskia River stretches 279.9 miles from its mouth at Mississippi River mile 117.6 to the agricultural drainage ditches west of Champaign, Illinois where it begins. The Kaskaskia River drains a total of 5,801 mi^2 covering 10.4 percent of the states surface area. Two large flood control reservoirs, Lake Carlyle and Lake Shelbyville, are located on the Kaskaskia River. The dams are located at river miles 94.2 and 197.9 upstream from the mouth, and have surface areas of 24,580 and 11,000 acres respectively. There are 26 AWQMN stations in this watershed including nine on the Kaskaskia River. Major tributaries to the Kaskaskia River include Silver Creek and Shoal Creek.

The smaller direct tributaries to the Mississippi River encompass 4,658 mi^2 in Illinois, nearly equaling in size the Kaskaskia River watershed. The Big Muddy River basin in southwestern Illinois, is the largest of these tributaries and drains 2,387 mi^2. The next largest direct tributary in terms of area is Henderson Creek which drains 604 mi^2 , followed by Edwards River (451 mi^2) and Bear Creek (392 mi^2). Drainage areas for the remaining direct tributaries is less than 300 mi^2.

The state of Illinois comprises a relatively small portion of the total drainage area of the Mississippi River. The United State Geological Survey (USGS) gaging station on the Mississippi River at Keokuk, Iowa, drains 119,000 mi^2 and has a mean discharge of 65,840 cubic feet per second (cfs). There are approximately 11,041 mi^2 of Illinois which drain into the Mississippi River upstream from the confluence with the Illinois River indicating that the Illinois portion of the drainage at Keokuk is approximately 9 percent. At the USGS station on the Mississippi River near Thebes, Illinois, 43.7 miles upstream from the confluence with the Ohio River, the Mississippi River drains 713,200 mi^2 and has a mean discharge of 205,100 cfs. The Illinois portion of the Mississippi River watershed at Thebes is approximately 6.3 percent of the

total area. By contrast, the Missouri River flows into the Mississippi River at river mile 195 just above St. Louis, Missouri, and drains 524,200 mi^2 or 73.5 percent of the of the watershed at Thebes. In regard to daily mean flows, the Illinois River has the highest mean daily discharge at 21,950 cfs, followed by the Rock River 9,659 cfs and Kaskaskia River 3,735 cfs.

The Ohio River basin is the other major drainage from the state of Illinois. The Ohio River, along with its tributary the Wabash River, forms the south and southeastern borders of the state of Illinois. Total drainage to the Ohio River basin from Illinois consists of 10,977 mi^2 or 19.7 percent of the state's total surface area. The Wabash River and its major tributaries, the Vermilion River, Embarras River, and Little Wabash River, drain the majority of this area: 8,599 mi^2 (78.3 percent). Direct tributaries to the Ohio River drain the remaining 2,378 mi^2 (21.7 percent). The largest tributary that drains directly to the Ohio River from Illinois is the Saline River, which has a drainage area of 1,177 mi^2. There are 37 AWQMN stations in the Ohio River watershed. In comparison to the Ohio River as a whole, the Ohio River at Metropolis, Illinois, located 37 miles upstream from the confluence with the Mississippi River, has a drainage area of 203,000 mi^2 and a mean discharge of 277,700 cfs. The Illinois portion of the Ohio River basin, in terms of surface area, is approximately 5.4 percent of the total.

A comparatively small amount of the state of Illinois, 670 $miles^2$, drains directly into Lake Michigan. However, water from Lake Michigan is pumped/diverted to the Des Plaines River at Lockport via the Chicago Sanitary and Ship Canal, and ultimately to the Illinois River, at the rate of 3200 cubic feet per second (cfs) (Changnon and Changnon, 1996).

2. DATA SOURCES

Historically, stream water quality data in Illinois has been collected by the Illinois State Water Survey (ISWS), the Illinois Department of Public Health, the Illinois EPA and the United States Geological Survey (USGS). This has resulted in a rich data set covering streams ranging in size from small agricultural drainage ditches to the Mississippi River. Since October 1977, the Illinois EPA has operated the most widespread, active long term monitoring network in Illinois which is known as the ambient water quality monitoring network (AWQMN). The current AWMQN network was preceded by a 538 station network operated by the Illinois EPA between water years 1972 and 1977 (note water years run from October 1 through September 30). Evaluation of the older data was presented in a series of reports prepared by the Illinois Water Information System Group, headed by Ronald Flemal and Donovan Wilkin (Peckham, 1980). Of the 538 original stations, 108 were incorporated into the current network. The change in stations in October 1977 reflected in part, the adoption of USGS sampling methodologies. Older stream water quality data, (i.e., from 1945 through 1971), has also been collected by the Illinois State Water Survey and the Illinois Department of Public Health at many of these stations (Winget, 1976). The Illinois EPA ambient water quality network was chosen as the basis for this study because it provided a statewide network, included the parameters necessary for the analysis, along with a consistent sampling method and analysis over an extended period of time.

The goals of Illinois EPA surface water monitoring programs are to identify causes of pollution (toxics, nutrients, sedimentation) and sources (point or nonpoint) of surface water impairments, determine the overall effectiveness of pollution control programs and identify long term resource quality trends. The AWQMN is utilized by the Illinois EPA to provide baseline water quality information, to characterize and define trends in the physical, chemical and biological conditions of the state's waters, identify new or existing water quality problems and to act as a triggering mechanism for special studies or other appropriate actions. Additional uses of the data collected by the Illinois EPA through the AWQMN program includes the establishment of water quality based effluent limits for NPDES permits. The AWQMN is integrated with other Illinois EPA stream monitoring programs, both chemical and biological, which are more localized geographically (specific watersheds or point source receiving stream) and cover a shorter span of time (e.g. one year) to evaluate compliance with water quality standards and to determine designated use supports as required in Section 305(b) of the Clean Water Act.

Description of Illinois EPA Ambient Monitoring

The present AWQMN was initiated in October 1977 and has consisted of 209 stations through September 1996 (Figure 2-1). It was operated in cooperation with the USGS through September 1992. Data collected by the Illinois EPA from 1978 through the 1992 water years were published by the USGS as part of the series, "Water Resources Data: Illinois Volumes 1 and 2." Results of concurrent and split samples collected by the two agencies during this time period have also been published (Melching and Coupe, 1995). More recent data, since October

Figure 2-1. Locations of Illinois EPA Ambient Water Quality Monitoring Network (AWQMN) stations. 1977 - 1998.

1992, have not been published by the USGS but are available upon request from the Illinois EPA or through STORET. Although no longer a cooperator with the USGS, the Illinois EPA has continued to transfer ambient water quality data to the USGS for inclusion in their databases.

As of September 1996, the AWQMN consisted of 202 stations throughout Illinois sampled nine times a year on a six week rotation and one station on the Mississippi River near Fulton, which was sampled quarterly, for a total of 203. Samples were collected randomly in regard to flow events and spills and therefore provide a good unbiased estimator of baseline loadings and concentrations. Active main stem sites in the AWQMN include nine stations on the Sangamon and Kaskaskia Rivers, eight stations on the Illinois River, seven stations on the Des Plaines River, six stations on the Fox River, five stations each on the Little Wabash and Rock Rivers, and four stations each on the Embarras River, Spoon River, and Big Muddy River. There are two stations each on the Mississippi River, Kankakee River, La Moine River, Vermilion River (Illinois), Mackinaw River, Green River and Macoupin Creek. The Illinois EPA AWQMN program included six different streams named Sugar Creek and two different Indian Creeks, Vermilion Rivers, Salt Creeks and Little Vermilion Rivers. There were six inactive stations at the beginning of this project (Table 2-1). However, more recent water quality data has been collected from the Mississippi River at Thebes (I 84) by the USGS and from the Wabash River at New Harmony (B 07) by ORSANCO.

Table 2-1. List of Inactive Illinois EPA AWMQN stations.

IEPA Station Code	Stream Name	21ILAMB Period of Record
A 06	Ohio River	1972-91
B 07	Wabash River	1974-87 (sampled by ORSANCO)
GI 01	Sanitary and Ship Canal	1987-92
I 84	Mississippi River	1983-95 (sampled by Missouri USGS)
J 05	Mississippi River	1989-95 (replaced J 83)
J 83	Mississippi River	1975-89

AWQMN station descriptions are located in Appendix Table A-1, and include the Illinois EPA stream code, corresponding USGS stream code, the stream name, county, drainage area, latitude and longitude and limited parameter information. The Illinois EPA utilized an alpha-numeric stream coding system consisting of four alphabetic characters, which indicate the stream being sampled, and two numeric characters which represent the station number on the stream. The state is divided into 14 major basins using this system (Table 2-2, Figure 1-1). The few streams which drain directly into Lake Michigan utilize the letter "Q" as a basin identifier. Letter designations are added alphabetically to major tributaries as one moves upstream from the mouth. For minor, direct tributaries, the second letter is always "Z." Therefore, the letter farthest to the right designates the stream name within a watershed. Station numbers reflect

primarily the stations establishment over time (the oldest stations are “01") and are not necessarily related to upstream-downstream position within the watershed drainage. For example station code DJBZ01 indicates:

D - Illinois River
J - Spoon River
B - Big Creek
Z - Slug Run
01 - station number “1" on Slug Run

Table 2-2 . List of Illinois EPA major basin designation codes.

A	Ohio River	I	Mississippi River (South)
B,C	Wabash River	J	Mississippi River (South Central)
D	Illinois River	K,L	Mississippi River (North Central)
DT	Fox River	M	Mississippi River (North)
E	Sangamon River	N	Big Muddy River
F	Kankakee River	O	Kaskaskia River
G,H	Des Plaines River	P	Rock River

Sample collection and analysis

AWQMN water quality samples were collected utilizing the equal width increment, equal transit rate method developed by the USGS (Guy and Norman, 1970). This method requires equal spacing of intervals across the stream cross section which varies with stream width, and an equal transit rate or constant speed of lowering and raising the sampler. The sampler utilized was dependent on water velocity and stream depth (Illinois EPA, 1987). Samples were composited in a churn splitter before being transferred to the appropriate collection bottles. Samples for dissolved parameters were obtained utilizing a 0.45 µm pore size filter. A summary of laboratory methods for the parameters used in this study is provided in Table 2-3. A universal parameter group (ASN01) is collected from all stations in the network and includes the following (STORET code) parameters: (20) air temperature, (10) water temperature, (299) field dissolved oxygen, (400) field pH, (94) field conductivity, (535) volatile and (530) total suspended solids, (610) total ammonia-N, (612) calculated unionized ammonia, (630) total nitrate +nitrite-N, (76) turbidity, (665) total and (666) dissolved phosphorus, (31616) fecal coliform, (900) hardness (calc.), along with total and dissolved metals (Table 2-4). Additional parameters, collected at selected stations, include (680) total organic carbon, (625) total Kjeldahl N, (940) total chloride, (945) total sulfate, (1002) total arsenic, (32730) phenol, (951) total fluoride, (720) total cyanide, (410) total alkalinity, (70508) total acidity and (71900) total mercury (Appendix Table A-2). Chemical oxygen demand, COD (335) and oil&grease(556), were dropped from the network in 1990. Total and dissolved phosphorus were added to all stations in 1984, although some stations may contain older data. Subnetworks for the monitoring of pesticides and industrial solvents were established in 1985 and 1988 respectively.

Table 2-3. Summary of Illinois EPA laboratory methods for analysis of selected water quality parameters.

Parameter	Preservative	Analysis Method	Unit of Measure	Reporting Limits
Total Nitrate+ Nitrite-Nitrogen	10 ml 20% H_2SO_4/l at 4 °C	Automated Cadmium reduction method with Flow Injection Analysis	mg/L	low at 0.02 mg/L high at 2 mg/L
Total Ammonia-Nitrogen	10 ml 20% H_2SO_4/l at 4 °C	Automated Phenate method on Continuous Flow Analyzer	mg/L	low at 0.01 mg/L high at 0.05 mg/L
Total Kjeldahl Nitrogen	10 ml 20% H_2SO_4/l at 4 °C	Block digestion, Automated Phenate method for ammonia	mg/L	0.1 mg/L
Total Phosphorus	10 ml 20% H_2SO_4/l at 4 °C	Digestion to orthophosphate, followed by ascorbic acid reduction method using Continuous Flow Analyzer	mg/L	low at 0.001 mg/L mid at 0.01 mg/L high at 0.1 mg/L
Total Suspended Solids	cool at 4 °C	Filtration on glass fiber filter, determination of increase in weight upon drying at 103-05 °C	mg/L	1 mg/L

Note: analysis methods have been consistent over the study period, October 1980 through September 1996.

Table 2-4. List of metals and their STORET codes, analyzed at all Illinois EPA AWQMN stations.

Total	Metal	Dissolved	Total	Metal	Dissolved
1105	Aluminum	1106	1051	Lead	1049
1007	Barium	1005	927	Magnesium	925
1022	Boron	1020	1055	Manganese	1056
1012	Beryllium	1010	1067	Nickel	1065
1027	Cadmium	1025	937	Potassium	935
916	Calcium	915	1077	Silver	1075
1034	Chromium	1030	929	Sodium	930
1042	Copper	1040	1082	Strontium	1080
1037	Cobalt	1035	1087	Vanadium	1085
1045	Iron	1046	1092	Zinc	1090

Data Storage

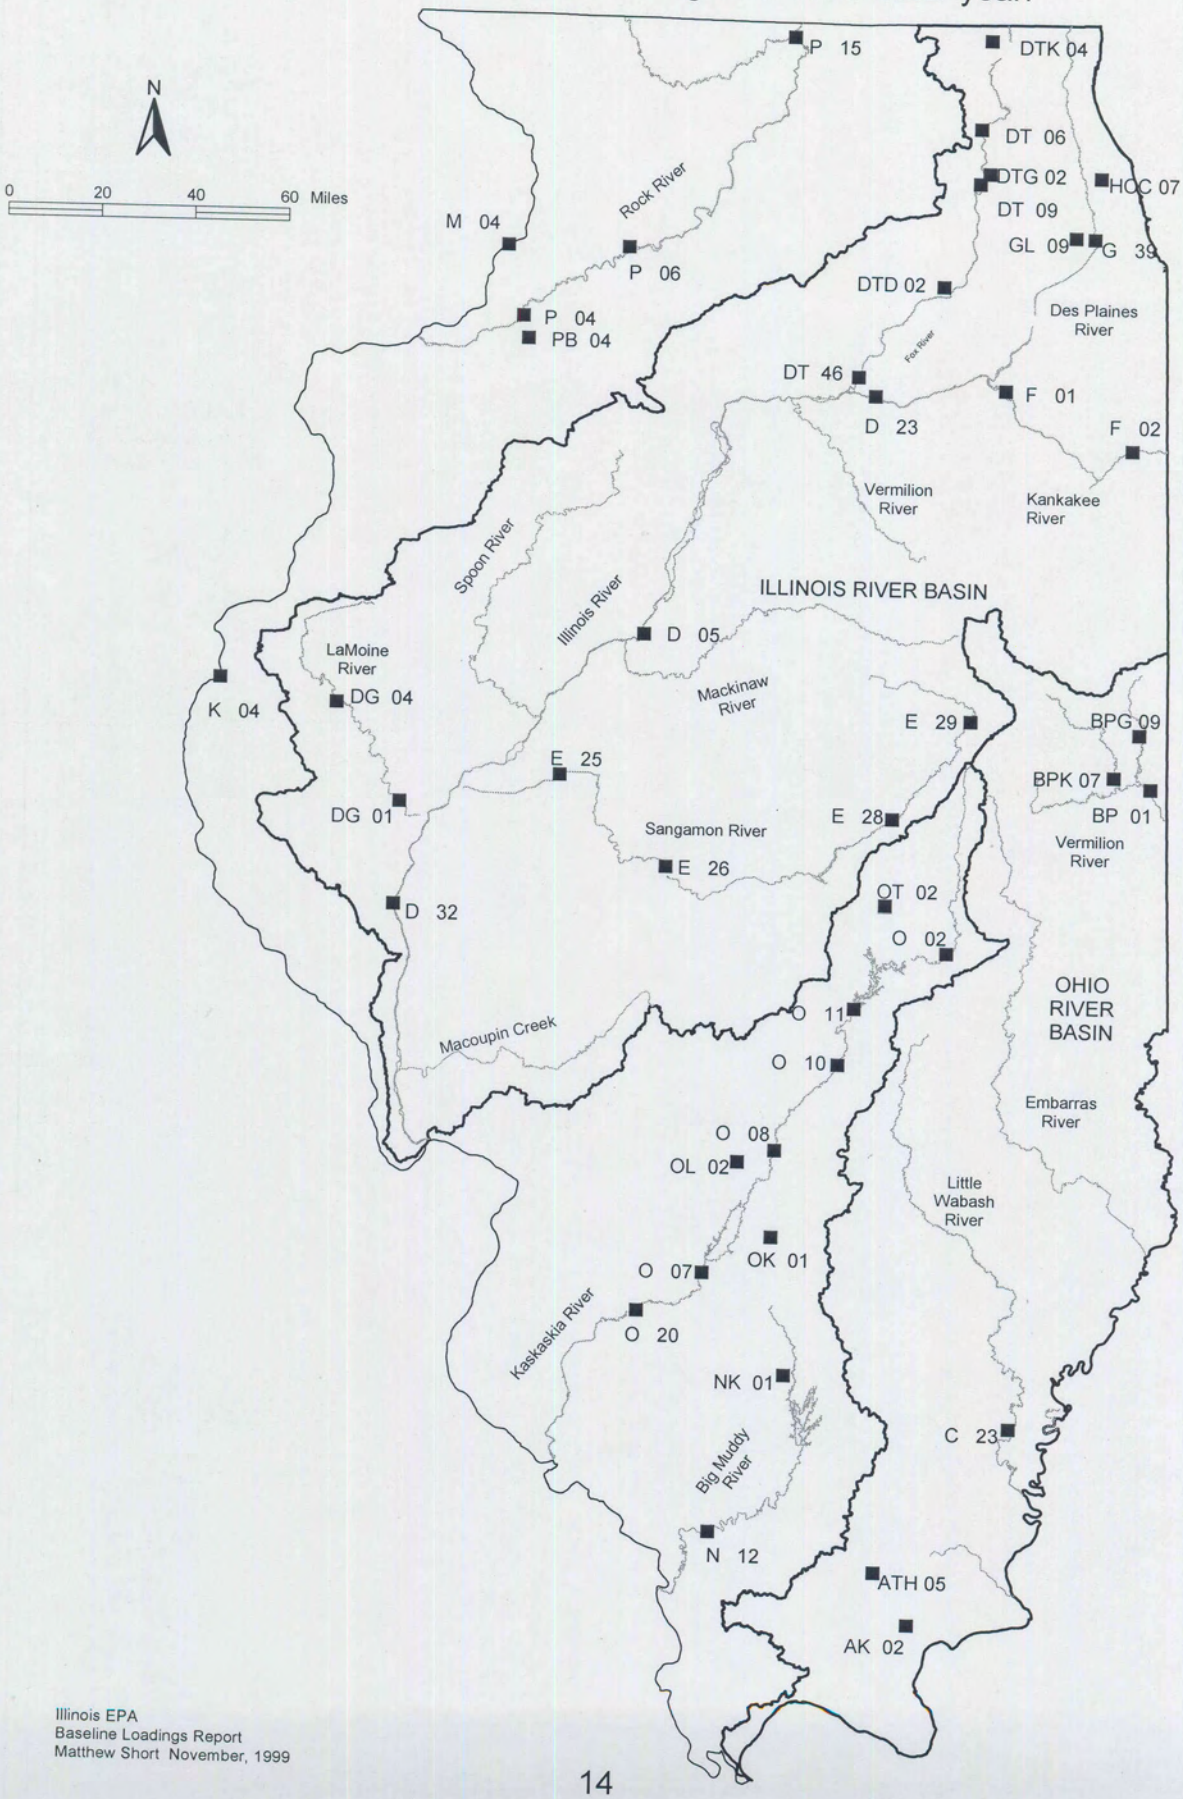
The Illinois EPA stores chemical data in a USEPA database known as STO (storage) RET (retrieval). Water quality data collected from AWQMN stations between October 1977 and December 1998 was stored in two separate STORET files: 21ILAMB and 21ILL. The 21ILAMB file contains data from the parameter groups for all 209 stations beginning in October 1977 or later depending on when the station was established. The primary station code for these stations is the USGS number. The unique Illinois EPA code is a secondary code. Nitrogen data in the 21ILAMB file includes total ammonia-N (610) and total nitrate + nitrite-N (630) at all stations for the period of record. Total Kjeldahl nitrogen or TKN (625) was available from 76 active stations along with all six of the inactive stations. USGS flow data in cubic feet per second (60 or 61) is also stored with the chemical data. USGS flow data through the 1996 water year was available at 98 of the active AWQMN stations. The combination of TKN, total nitrate+nitrite-N and flow, which are the parameters necessary to calculate total nitrogen loads, were available from 43 active stations (Figure 2-2).

The 21ILL file in STORET contains a mixture of stream water quality and biological data from the AWQMN, special surveys and intensive surveys totaling 2,164 stations. Of these, 153 stations corresponded with current AWQMN stations. In relation to nutrient data needed for this study, 31 of the ambient stations in 21ILL contain only biological data (fish, macroinvertebrate, instream habitat); 44 have both biological and nutrient water quality data; and 78 contained only older ambient nutrient water quality data, collected prior to 1977. Total ammonia-N results from the 1972 to1977 ambient data is stored under a different STORET code (81213) than the more current ammonia data (610). Samples of total Kjeldahl nitrogen and stream flow data occur sporadically in the older data set. Other nutrient parameter codes stored with the older (pre-1977) data include total PO_4 (650), ortho P (660), dissolved NH_4 (71846) and dissolved NO_3 (71851). Metals data collected between 1972 and 1977 also utilized different STORET codes. The codes were referred to as “Illinois” codes and ranged between 81209 (Boron Illinois) and 81222 (Nickel Illinois). Metals data stored under these codes was reported in mg/L, rather than µg/L, which was used after 1977. The 21ILL file was also used to store industrial solvent and pesticide data collected as part of the post-1977 AWQMN. A portion of the Illinois State Water Survey data set is also available in STORET under file 21ILLSWS.

Data calculations

Although the current network was started in October 1977, several stations were phased in over the next several years. In order to utilize a consistent period of record for this study, an October 1980 begin date was selected. The end date, September 1996, was based on the availability of USGS flow data at the beginning of the project. This resulted in a 16 year period of record for the analysis. Prior to calculations, the chemical data set was reviewed for outliers and zero values. Some of the older water quality data, prior to1982, contained zero values. Discussions with Illinois EPA laboratory personnel indicated that these zero values indicated less

Figure 2-2. Illinois EPA AWQMN stations with TKN and flow data through the 1996 water year.



Illinois EPA
Baseline Loadings Report
Matthew Short November, 1999

than detection limits. These values were replaced with the appropriate detection limit value prior to calculations. Values reported at the detection limit, particularly total ammonia-N, were not adjusted for the initial summaries. Stream flow data, which is necessary for load calculations, were based on USGS data which had been stored with the water quality data. Most of the data was transferred to STORET using a computer program which accessed the data from WATSTORE after it had been verified by the USGS. The data contained both daily mean flows, particularly for post 1992 data, and instantaneous flows at the time of the sample, primarily in the pre-1992 water year data. On some ungaged tributaries, the USGS also supplied calculated flows based on relationships with adjacent watersheds and historical data through the 1992 water year. Due to the large volume of flow data, a thorough check to verify the accuracy of the flow numbers was not practical. However, zero flow values were verified and left in the analysis where they indicated no flow conditions. Flow values used in the regression analysis (Section 5) were based on a retrieval of USGS historical flow data via the Internet. Flow values from these stations were verified against the USGS daily mean flows.

Summary statistics of concentrations and loads (in pounds per day) were calculated using a STORET "MEAN" program. Data summaries of individual stations which include the number of samples, minimum, maximum, mean, standard deviation, variance, sum and percentiles (10^{th}, 25^{th}, 50^{th}, 75^{th}, 85^{th}, 90^{th}, 95^{th}) are provided for both concentrations and loads, and are located in Appendix B and C respectively. Baseline yields were calculated by dividing the mean load by the drainage area. Box plots are used throughout the report to show comparisons over time. The box ends represent the 25^{th} and 75^{th} percentiles of the data, the "tails" represent the 10^{th} and 90^{th} percentiles of the data. Means are represented by solid lines. In order to illustrate spatial variability, mean concentrations were extrapolated from watersheds where AWQMN stations were located to watersheds that were either upstream or adjacent that were unmonitored. Maps were generated using ArcView based on coverages developed by the Illinois EPA.

Testing for significant differences between monthly and annual means on the data set as a whole was done using SAS PROC GLM procedure within STORET (SAS, 1985). The GLM procedure uses the method of least squares to fit general linear models. An ANOVA F-test was used to determine if the monthly or annual means were significantly different from each other. Data was grouped by calendar year rather than water year for this analysis and therefore included data from January 1980 through December 1996. The null hypothesis (H_o) was that there were no significant differences between the means at the $p< 0.05$ level. Although the Anova F-test can indicate that a significant difference exist, it does not indicate which means differ from each other. A "MEANS" statement was added to the GLM in order to provide a clearer separation of means through multiple comparison methods. Although there is no general agreement on what method works best, both the Tukey studentized range test and Duncan multiple range tests were used. In addition to testing the statewide data set, the PROC GLM method was applied to individual stations within selected watersheds to test for significant differences in means of the constituents. These included the main stem Illinois River stations, the Sangamon River basin and the Kaskaskia River basin.

3. SPATIAL COMPARISONS OF SELECTED PARAMETER CONCENTRATIONS

Total Ammonia Nitrogen

Total ammonia as nitrogen, which includes both NH_4-N and NH_3-N, ("ammonia") concentrations were examined from 29,681 samples collected between October 1980 and September 1996. Prior to 1990, the reported detection limit of ammonia was either 0.01 or 0.10 mg/L, depending on which Illinois EPA laboratory conducted the analysis. On samples collected after June1990, the detection limit reported in the data was standardized to 0.01 mg/L. The summary statistics generated for total ammonia-N were based on the detection level reported in the data. The statewide mean was 0.32 mg/L (±0.0058) (mean ± standard error of the mean) Table 3-1. Concentrations were less than or equal to 0.10mg/L, the higher reported detection level, in 54 percent of the samples. The maximum value, 34 mg/L, was collected on the Sangamon River near Niantic, Illinois (E 05) in September 1982. This station had nine other samples which exceeded the 15 mg/L general use water quality standard maximum for ammonia in the early 1980s. Other stations which exceeded the 15 mg/L maximum included Saline Branch near Mayview (BPJC06), Casey Fork near Mt. Vernon (NJ 07), Silver Creek near Troy (ND 06), Richland Creek near Hecker (OC 04), and Canteen Creek near Horseshoe Lake (JNA 01). Elevated ammonia concentrations at these stations were the result of wastewater treatment plant discharges in these instances. Spatial distributions of ammonia concentrations primarily reflected the effects of urban areas and their associated wastewater treatment plants (Figure 3-1).

Table 3-1. Statewide summary statistics for nutrient parameters and total suspended solids collected between October 1980 and September 1996, Illinois EPA AWQMN data.

Statewide:	Total Ammonia-N	T. Nitrates+ nitrites-N	Total Kjeldahl-N	Total Phosphorus	Dissolved Phosphorus	TSS
Mean	0.31574	3.8872	1.3886	0.3791	0.2522	80.628
Std Error	0.0058	0.0223	0.0134	0.0041	0.0038	1.3210
Median	0.100	2.70	1.10	0.200	0.090	36.0
95^{th}Percentil	1.00	11.5	3.30	1.30	1.07	255
99^{th}Percentil	4.60	15.0	7.20	3.00	2.70	850
Number	29,681	29,550	11,751	26,224	25,555	29,641

Statewide, mean ammonia concentrations showed statistically significant differences in both monthly and annual comparisons (Figure 3-2, Table 3-2). Mean ammonia concentrations were significantly higher in the months of January and February and reflected a steady decline into the month of June when the concentration began increasing. Efforts within the state of

Figure 3-2. Comparison of statewide total ammonia-N concentrations from Illinois EPA AWQMN data, October 1980 through September 1996.

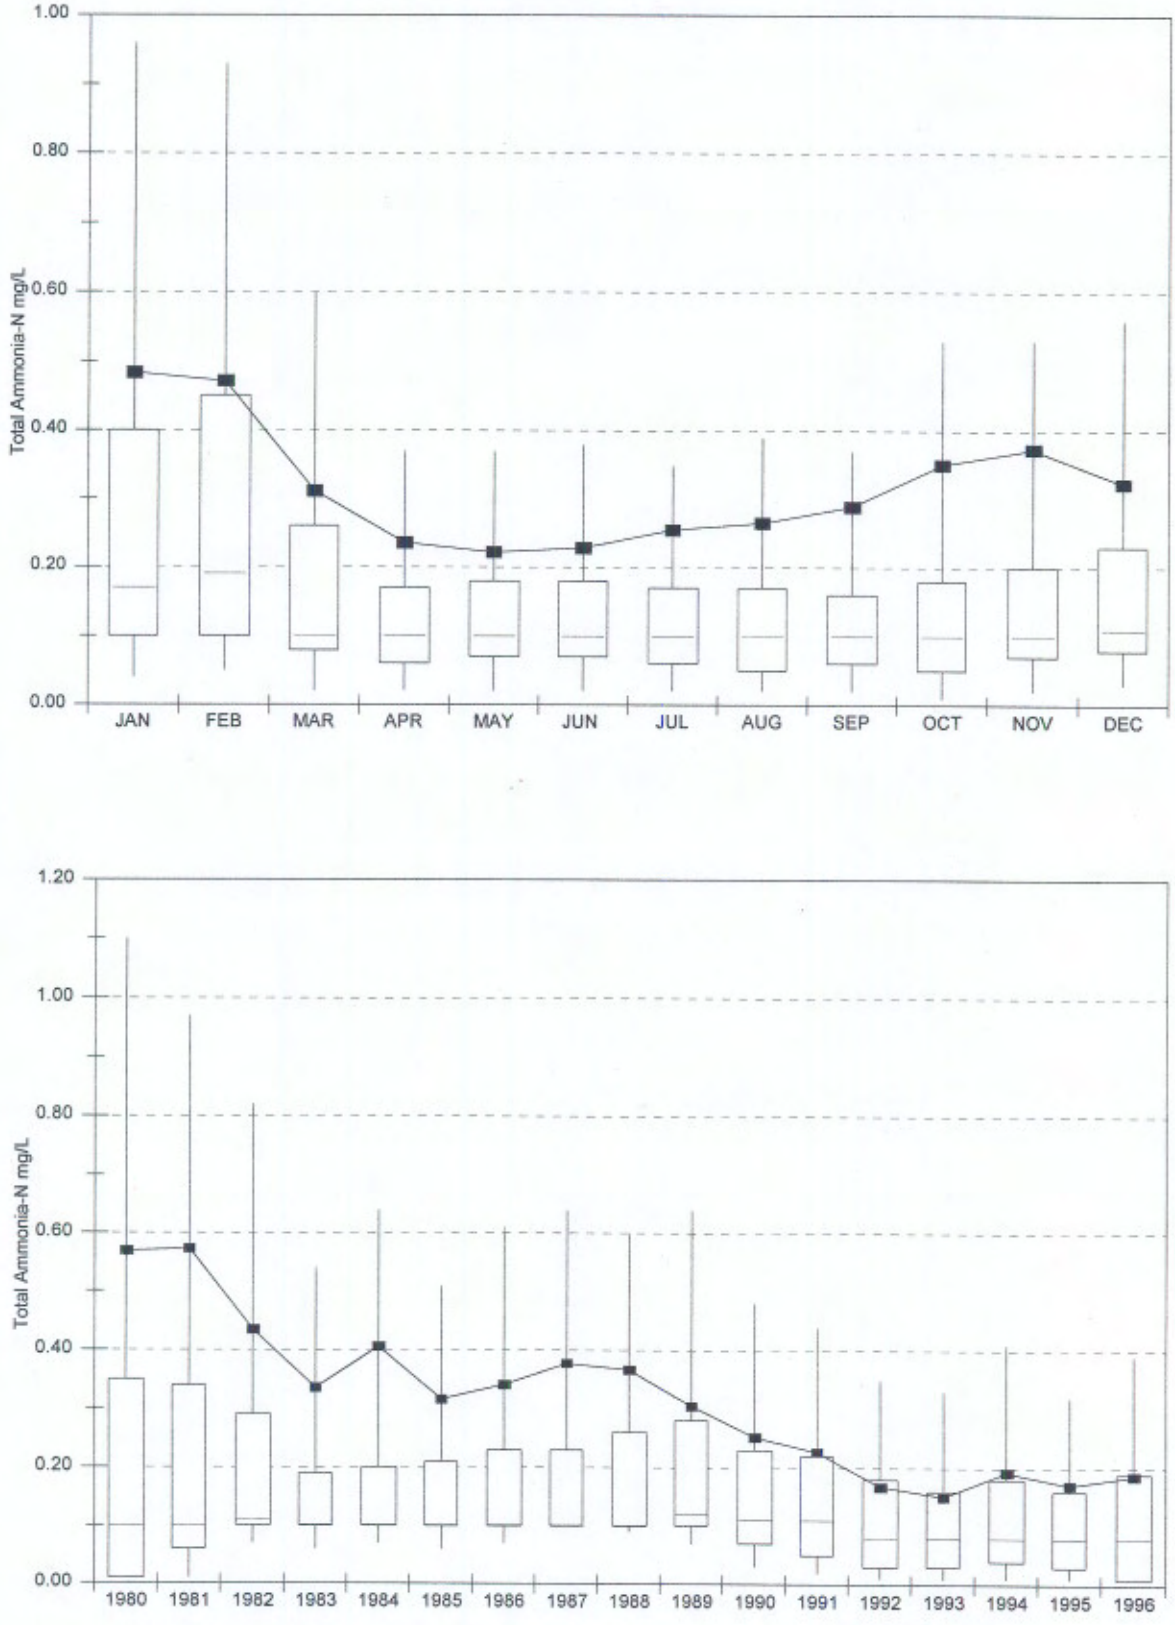


Figure 3-1. Distribution of mean total ammonia-N concentrations by watershed.

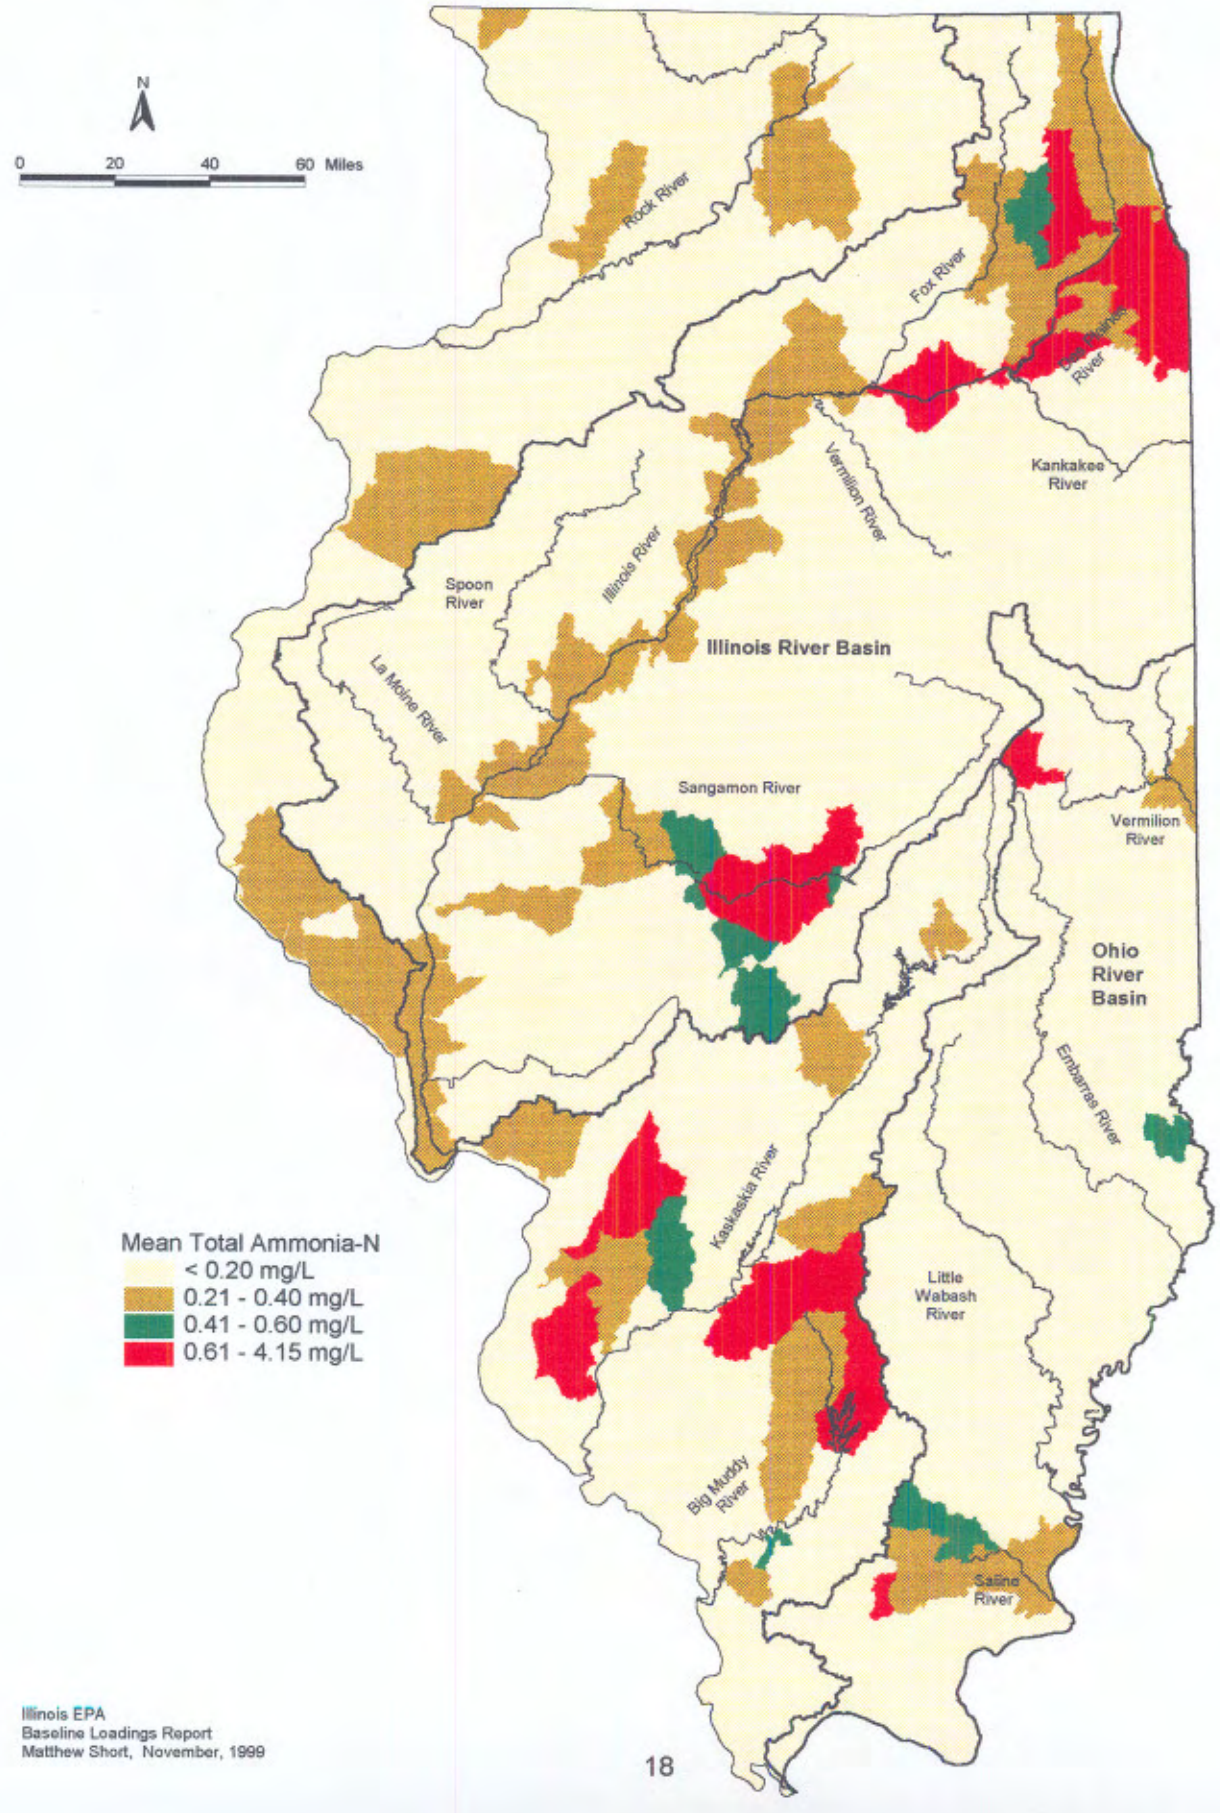

Illinois EPA
Baseline Loadings Report
Matthew Short, November, 1999

Illinois to reduce ammonia discharges to streams through improved wastewater treatment, were reflected in the significant decline in the overall statewide mean concentration over the 16 year period of record. Because the variability in the detection level in the pre-1990 data could have affected the declining trend, ammonia concentrations were normalized to a consistent detection level. All values at or less than 0.10 mg/L (the highest reported detection limit) were set equal to 0.10 mg/L. The adjusted data followed the same declining trend line as the unadjusted data (Figure 3-2).

At individual stations, mean concentrations of ammonia ranged from less than 0.10 mg/L at 25 stations to 4.15 mg/L on the Cal-Sag Channel (H 01). Of the 203 active stations, 107 had mean ammonia concentrations between 0.11 and 0.20 mg/L; 28 had mean concentrations between 0.21 and 0.30 mg/L; and 15 had mean concentrations between 0.31 and 0.40 mg/L. Streams which had highest mean concentrations of ammonia included the Chicago Sanitary and Ship Canal, 2.3 mg/L (GI 02); the Sangamon River near Niantic, 2.8 mg/L (E 05) and Roby, 1.5 mg/L (E 16); Casey Fork near Mt. Vernon, 2.3 mg/L (NJ 07); and Canteen Creek southeast of

Table 3-2. Summary of results from PROC GLM procedure in SAS. The null hypothesis (H_o) was that there was no significant difference in means between years or months.

	Parameter	F - value	Pr > F
By Month	Total Ammonia	19.71	0.0001
	TKN	4.63	0.0001
	Total Nitrates	164.59	0.0001
	Total Phosphorus	33.62	0.0001
	Dis. Phosphorus	41.48	0.0001
	TSS	53.41	0.0001
By Year	Total Ammonia	34.26	0.0001
	TKN	13.30	0.0001
	Total Nitrates	32.21	0.0001
	Total Phosphorus	10.85	0.0001
	Dis. Phosphorus	13.72	0.0001
	TSS	17.34	0.0001

Horseshoe Lake, 2.2 mg/L (JNA 01). In general, stations with mean ammonia concentrations greater than 0.40 mg/L were downstream from the influences of urban areas or wastewater treatment plants. The exception to this was Sugar Creek near Creal Springs (ATHG01) a

tributary to the South Fork Saline River in the Ohio River basin, where the mean ammonia concentration was 0.88 mg/L. This stream, impacted by acid mine runoff from abandoned strip mines, is often acidic and generally devoid of aquatic life. These factors probably affected this stream's ability to assimilate or nitrify ammonia.

In the Rock River basin, mean total ammonia-N concentrations at individual stations ranged from 0.07 on the Green River (PB 02) to 0.28 on the Kyte River (PL 03) and Kilbuck Creek (PQB 02). On the five Rock River stations, mean total ammonia-N concentrations ranged from 0.15 to 0.21 mg/L.

The farthest downstream station on the Des Plaines River (G 23) exhibited a mean total ammonia-N concentration of 1.73 mg/L. On the Des Plaines River at Lockport (G 11), upstream from the confluence with the Chicago Sanitary and Ship Canal, the mean total ammonia-N concentration was 0.30 mg/L. The elevated ammonia concentrations on the Des Plaines River, below the confluence with the Chicago Sanitary and Ship Canal, affected levels in the Illinois River at Marseilles (D 23) which had a mean value of 0.62 mg/L. In contrast, the mean total ammonia-N concentration in the Kankakee River near Wilmington (F 01), which along with the Des Plaines River form the Illinois River, was 0.10 mg/L. Concentrations of total ammonia-N in the Illinois River decreased with distance from Chicago due to the oxidation of total ammonia-N to nitrate+nitrite, along with dilution from the Fox River, Vermilion River and other tributaries. The mean total ammonia-N concentration on the Illinois River at Hennepin (D 16) was 0.38 mg/L (Figure 3-3).

On the nine Kaskaskia River stations, mean ammonia concentrations ranged from 0.10 to 0.20 mg/L. On tributaries to the Kaskaskia River, mean ammonia concentrations were less than 0.25 mg/L with the exception of Richland Creek 1.57 mg/L (OC 04); Crooked Creek 0.69 mg/L (OJ 07 and OJ 08); and Sugar Creek 0.57 mg/L (OH 01). These stations were downstream of Bellville, Salem, Centralia and Trenton respectively.

On the smaller direct tributaries to the Mississippi River, mean ammonia concentrations were less than 0.25 mg/L with the exception of Canteen Creek (see above); Harding Ditch 0.35 mg/L (JMAC02) and Henderson Creek 0.31 mg/L (LD 02). On the Mississippi River, ammonia concentrations were similar near Fulton, 0.14 mg/L (M 04), Keokuk, 0.15 mg/L (K 04) and Thebes, 0.14 mg/L (I 84).

In the Ohio River drainage, mean ammonia concentrations were less than 0.20 mg/L on 27 of the 35 stations sampled. Following Sugar Creek (ATHG01 see above) mean ammonia concentrations were 0.87 mg/L on Saline Branch near Mayview (BPJC06); 0.52 mg/L on Middle Fork Saline River near Harrisburg (ATG 03); and 0.46 mg/L on Sugar Creek (BF 01) near Palestine, Illinois (Figure 3-4).

Figure 3-3. Mean total ammonia-N concentrations (mg/L) on the Illinois River and the farthest downstream monitoring station on major tributaries. Illinois EPA AWQMN data, October 1980 - September 1996.

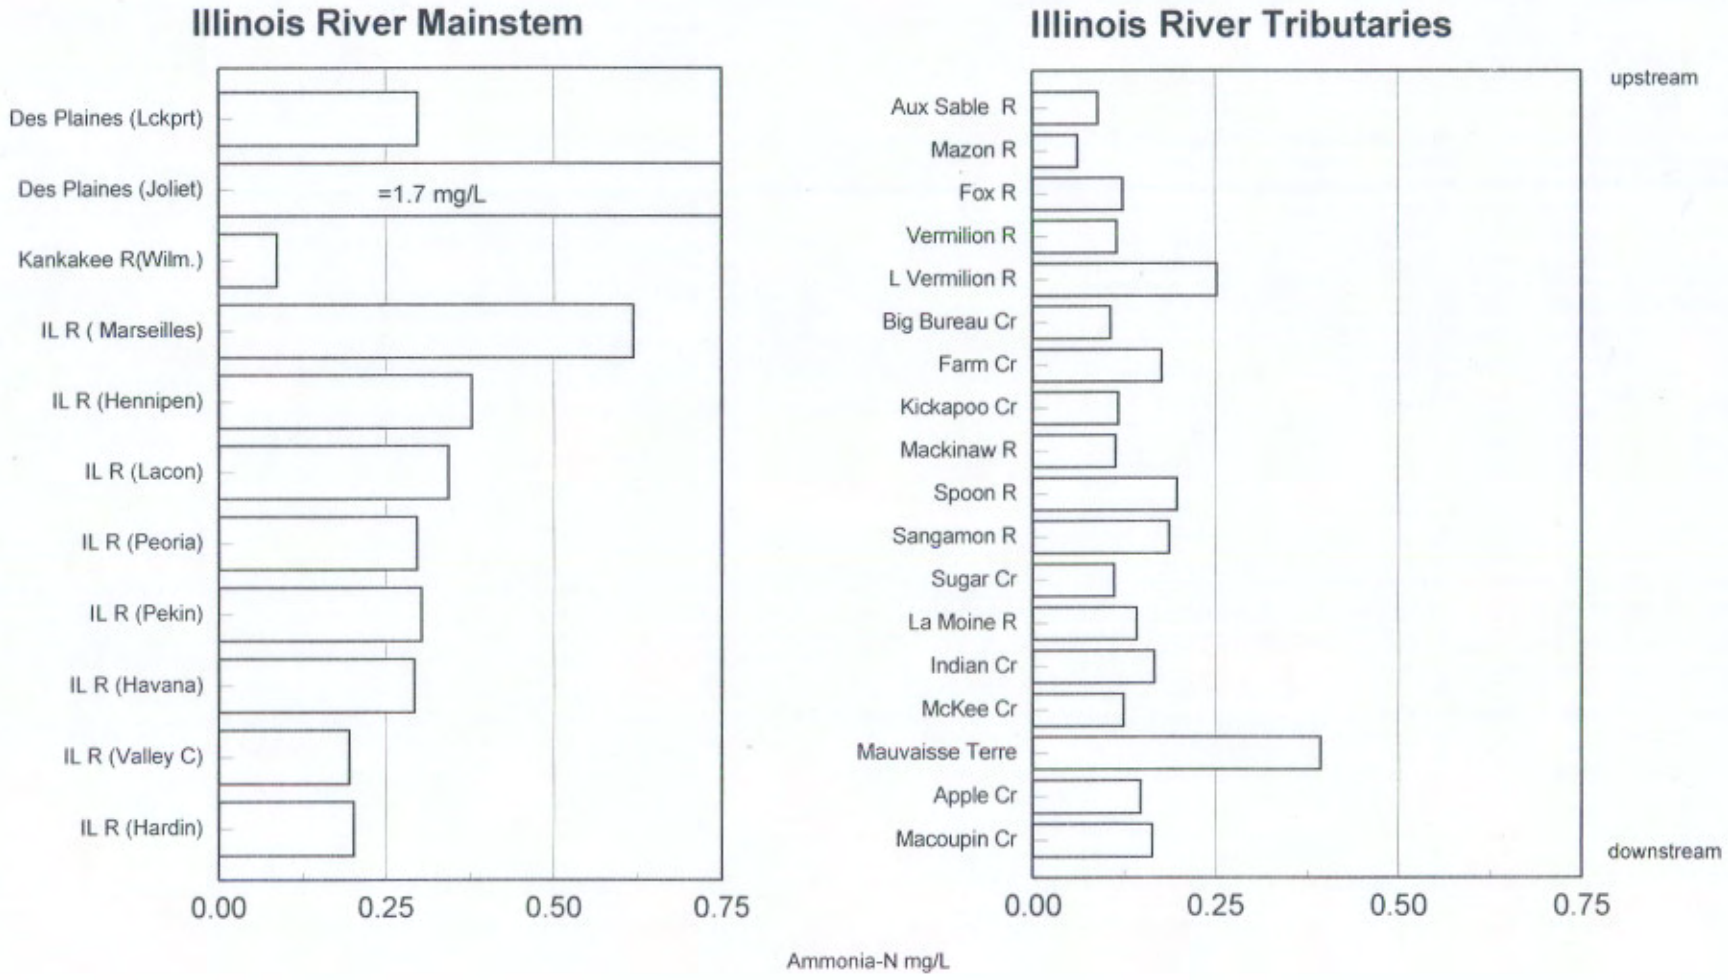

Figure 3-4. Mean total ammonia-N concentrations (mg/L) at the farthest downstream monitoring station on tributaries to the Ohio River, the Mississippi River and its tributary stations. Illinois EPA AWQMN data October 1980 - September 1996.

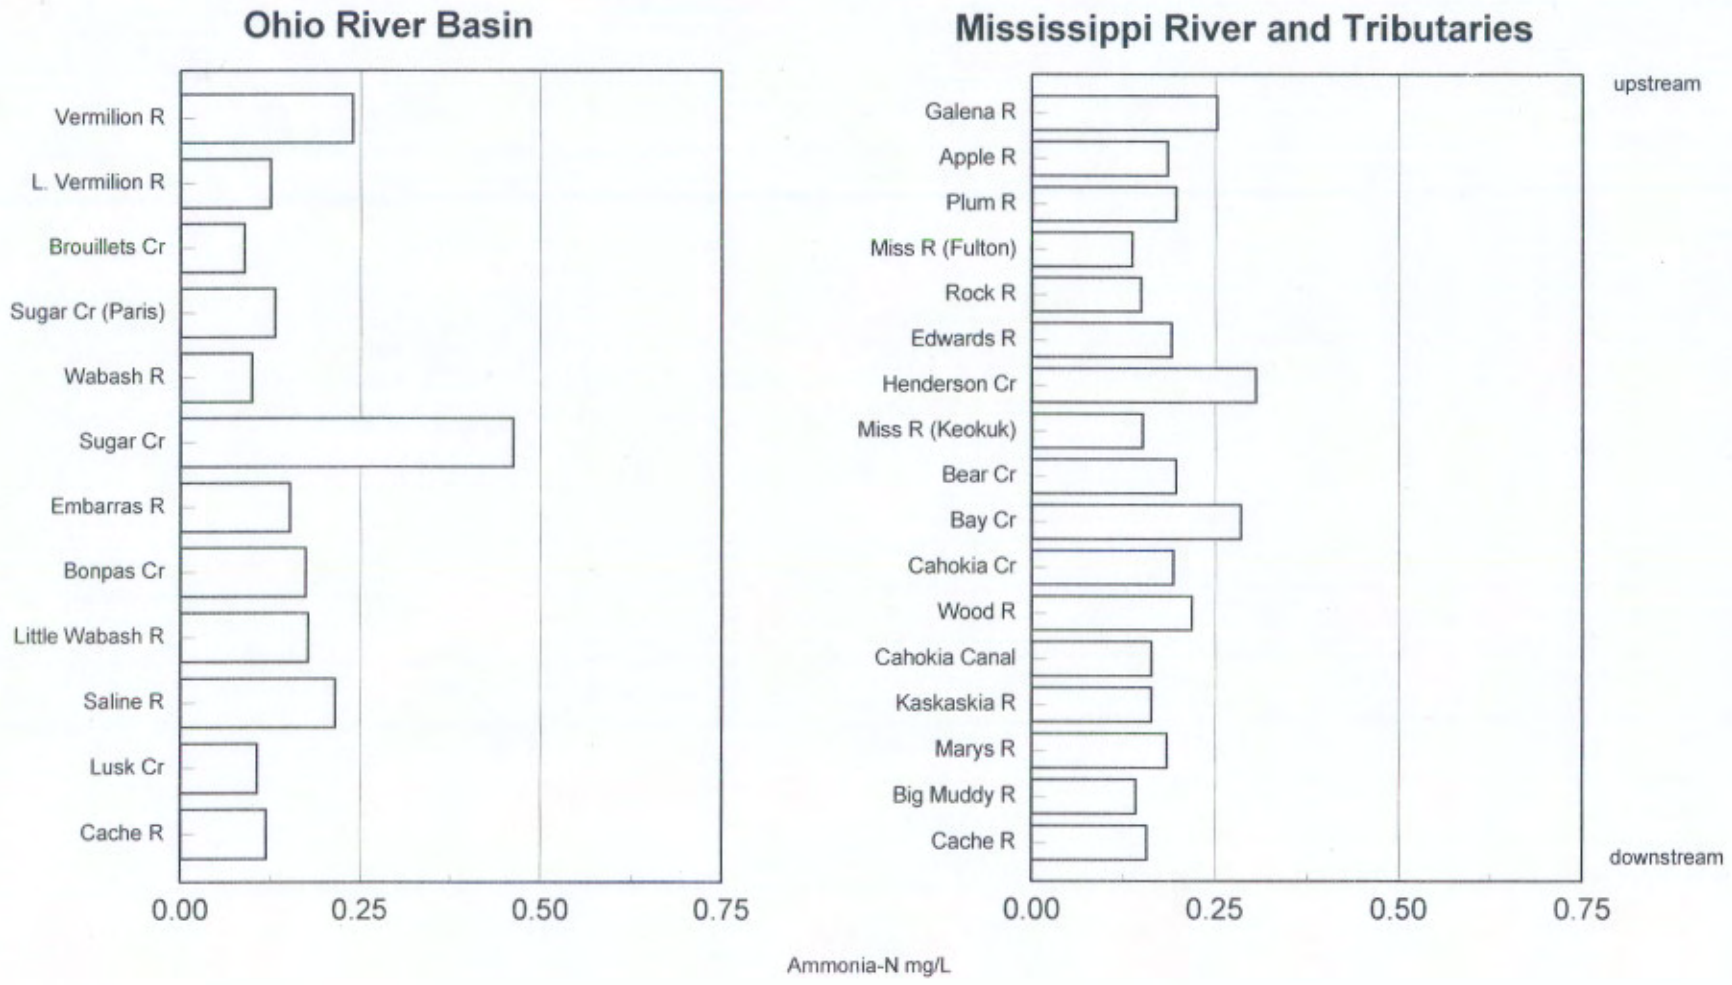


Total Nitrate+Nitrite Nitrogen

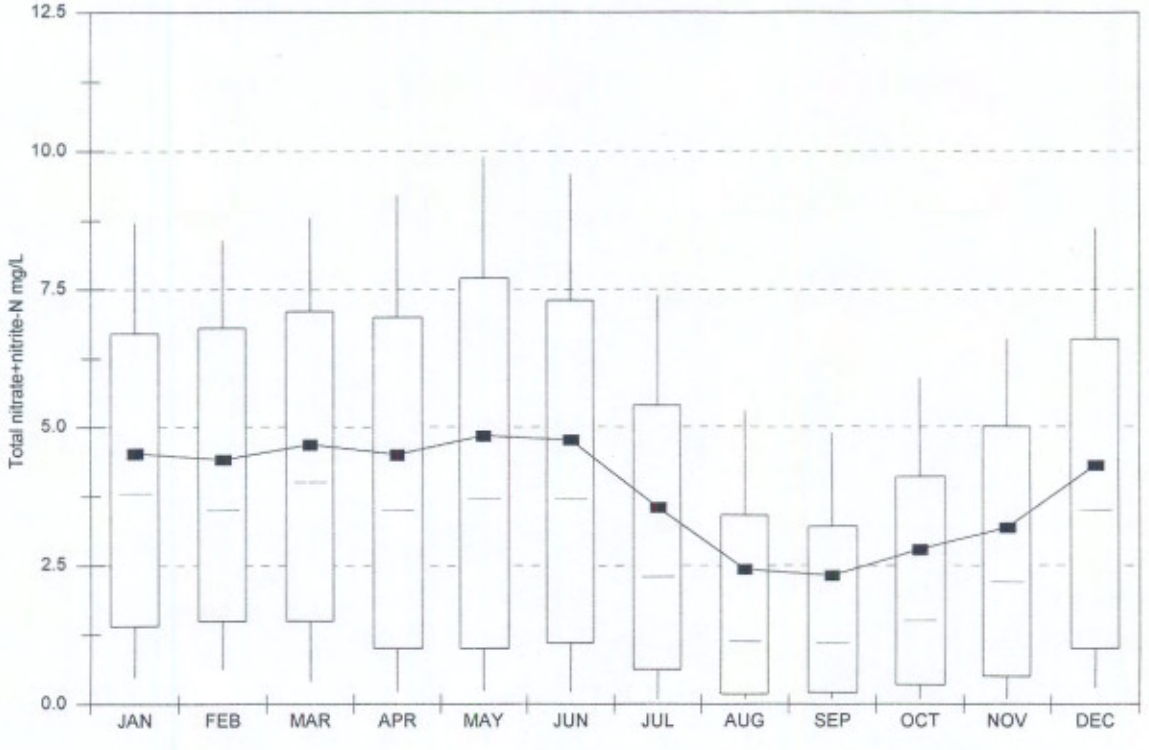
Total nitrate+nitrite-N ("nitrates") concentrations were examined from 29,550 samples collected between October 1980 and September 1996. The statewide mean was 3.89 (±0.0223) mg/L (Table 3-1). Concentrations were less than or equal to 1.0 mg/L in 30.6 percent of the samples. The maximum value in the data set, 88 mg/L, occurred from one sample on Yellow Creek (PWN 01) in the Rock River basin and may be an error. The next highest value was 34 mg/L from the Sangamon River near Monticello on August 1, 1991. Approximately 8.6 percent of the samples in the data set were equal to or greater than 10 mg/L.

Several studies have shown that nitrate concentrations in Illinois streams generally show significant seasonal variations at individual stations. The highest concentrations tend to occur in the spring and the lowest levels in the late summer, generally August or September (Crown and Flemal, 1978, and Short, 1995). Significant differences between monthly means were also evident in the statewide data set (Table 3-2). The pattern which exists at individual stations also held true for the statewide data set (Figure 3-5). Significant variations in the statewide annual mean also occurred (Table 3-2, Figure 3-5). The lowest annual means occurred during 1987 and 1988, corresponding with below average rainfall conditions during this time span. Annual mean concentrations peaked in 1990. Unlike mean ammonia concentrations, mean nitrate concentrations did not show significant spatial distributions based on the influence of wastewater treatment plant discharges. The spatial pattern of mean nitrates reflected a broader geographical influence. Means were generally highest (≥6.0 mg/L) in a band across the northern and central portions of the state. In contrast, most of the streams in the southern third of Illinois, such as the Big Muddy River and its tributaries, had low mean nitrate concentrations, generally ≤1.0 mg/L (Figure 3-6).

On the Rock River basin, mean nitrate concentrations at individual stations ranged from 3.5 mg/L on the Kishwaukee River (PQ 10) to 9.9 mg/L on Yellow Creek (PWN 01) (note excluding the 88 mg/L sample from the Yellow Creek data set would decrease the mean to 9.3 mg/L). In addition to Yellow Creek, high mean nitrate concentrations were present on Elkhorn Creek, 9.5 mg/L (PH 16); Kilbuck Creek 9.1 mg/L (PQB 02); South Branch Kishwaukee River 8.3 mg/L (PQC 06); Kyte River, 7.5 mg/L (PL 03); and Rock Creek, 7.3 mg/L (PE 05). On the five Rock River stations, mean nitrates ranged from 3.6 to 4.3 mg/L and were highest where the Rock River enters Illinois from Wisconsin (P 20).

On the Illinois River mean nitrate values ranged from 4.1 mg/L at the downstream station near Hardin (D 01) to 4.7 mg/L near Hennepin (D 16). Although mean nitrates on the Illinois River appeared similar, statistically, they were significantly different at the 95 percent level ($F=2.24$, $p=0.029$). Mean nitrate concentrations on the farthest downstream stations on the Des Plaines River (G 23) and Kankakee River (F 01), which form the Illinois River, were similar at 3.5 mg/L and 3.6 mg/L respectively (Figure 3-7). The increase in mean nitrate concentrations in the Illinois River at Marseilles over the lower stations on the Kankakee and Des Plaines Rivers was probably due to the oxidation of high total ammonia-N levels in the Des

Figure 3-5. Comparisons of statewide concentrations of total nitrate+nitrite-N from Illinois EPA AWQMN data. October 1980 through September 1996.



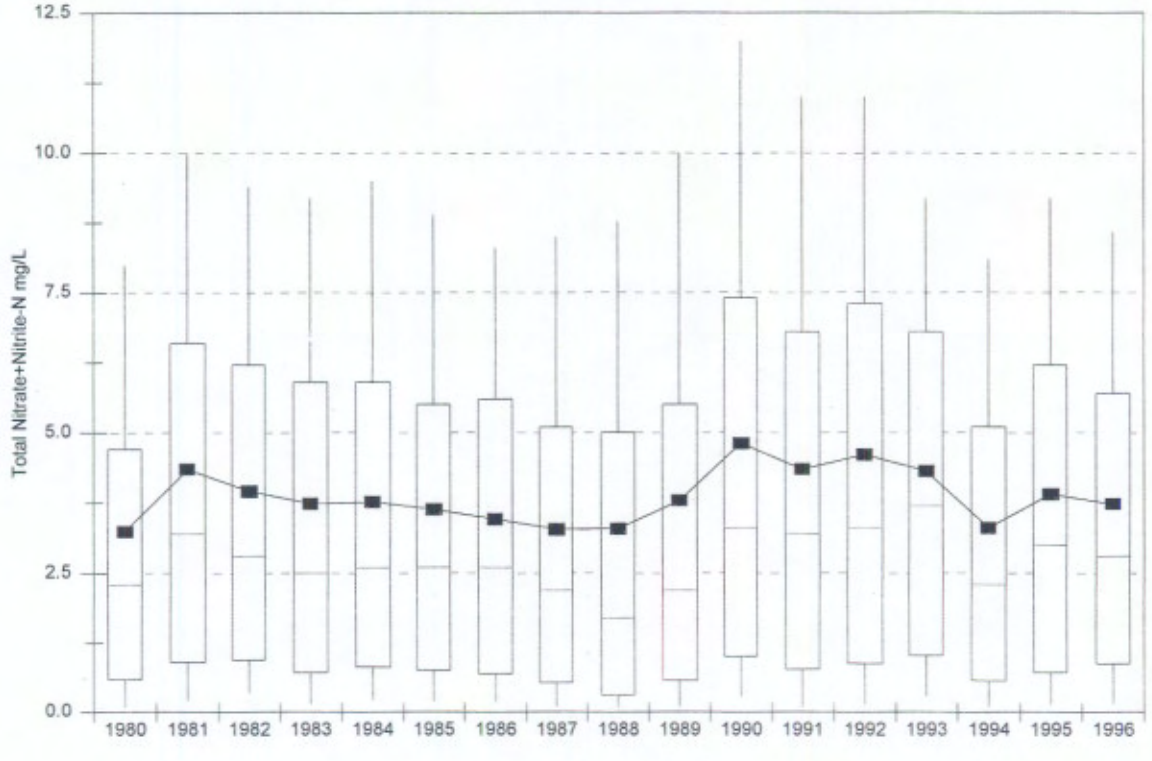


Figure 3-6. Distribution of mean total nitrate + nitrite-N concentrations by watershed.

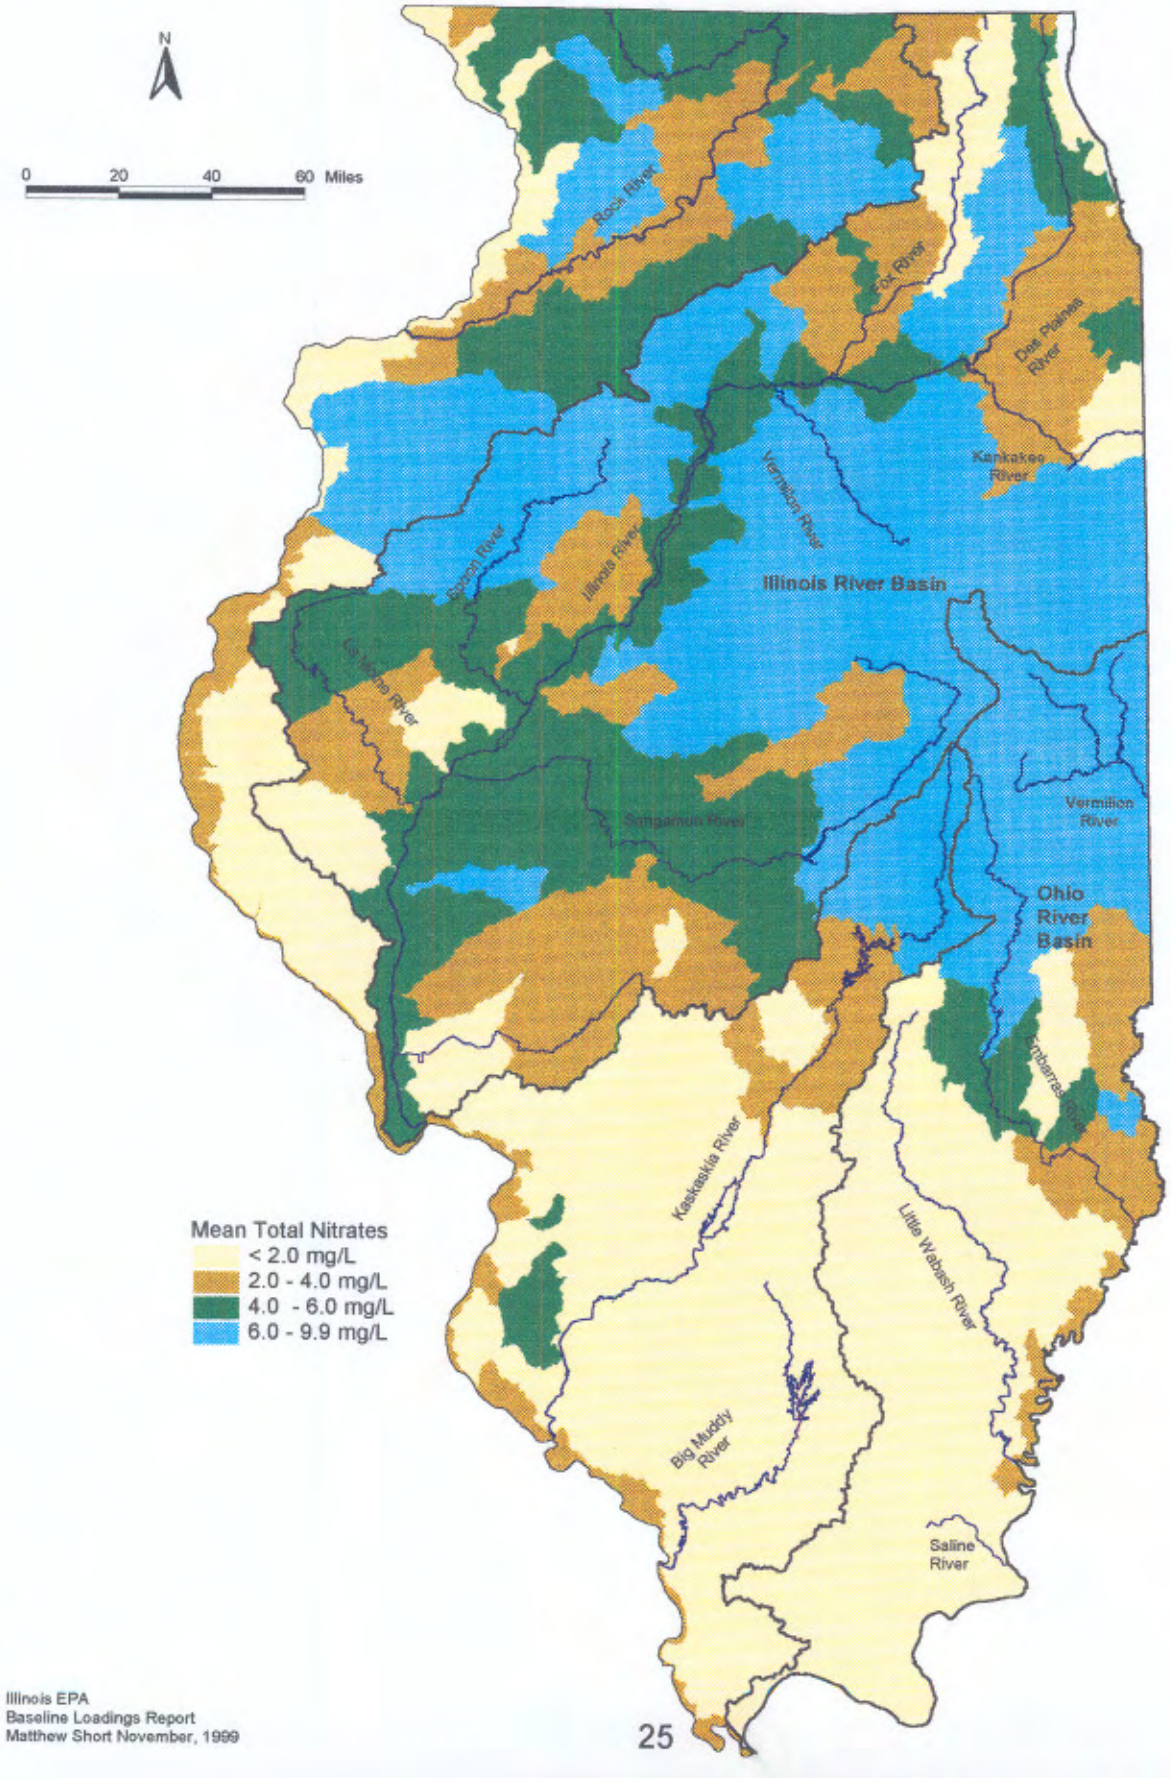

Illinois EPA
Baseline Loadings Report
Matthew Short November, 1999

Plaines to nitrate+nitrite-N. Although the smaller direct tributaries which flow into the Illinois River in this stretch have high nitrate concentrations, their influence, due to flow volume, is considered minimal. The Mazon River (DV 04), where mean nitrate concentrations were 8.8 mg/L, makes up only 3 percent of the flow volume of the Illinois River at Marseilles. Mean nitrate concentration on the Aux Sable River (DW 01), another small tributary, was 9.2 mg/L.

On tributaries to the Illinois River, the highest mean nitrate concentrations occurred in the tributaries located between the Des Plaines/Kankakee confluence and the bend at Hennipin (D 16). These included the Mazon and Aux Sable Rivers previously mentioned along with Bureau Creek, 8.9 mg/L (DQ 01) and its tributary West Bureau Creek, 9.9 mg/L (DQD 01); and the Vermilion River, 8.9 mg/L at DS 07 and 8.6 mg/L at DS 06. Mean nitrate concentrations on the Fox River were significantly lower than other tributaries in this reach. Concentrations ranged from 2.0 mg/L where the Fox River enters Illinois from Wisconsin (DT 35) to 3.1 mg/L near Dayton (DT 46) before it enters the Illinois River. Mean nitrate concentrations on tributaries to the Fox River ranged from1.1 mg/L on Poplar Creek near Elgin (DTG 02) to 4.5 mg/L on Somonauk Creek (DTB 01)

Other Illinois River tributaries which had high mean nitrate concentrations included the upper Mackinaw River, 9.6 mg/L (DK 13); and Indian Creek, 8.2 mg/L (DJL 01) a tributary to the Spoon River (DJ). Mean total nitrates exceeded 6.0 mg/L on stations located in the upper Sangamon River (E 28 and E 29) and tributaries Sugar Creek (EID 04) and Kickapoo Creek (EIE 04); the Spoon River (DJ 06 and DJ 02); Mauvaisse Terre Creek (DD 04); the Iroquois River (FL), a tributary to the Kankakee; the DuPage River (GB), West Branch and East Branch Du Page River, Salt Creek (GL) which are all tributaries to the Des Plaines River. There were two Illinois River tributaries which had mean nitrate concentrations that were less than 1.0 mg/L: McKee Creek (DE 01) a direct tributary to the Illinois River, 0.88 mg/L; and Slug Run (DJBZ01), a tributary to the Spoon River, 0.26 mg/L (Figure 3-7). On Slug Run, low nitrate concentrations are probably related to the fact that the watershed is an old strip mine area. McKee Creek, on the other hand, is a primarily agricultural watershed in west central Illinois.

Mean nitrate concentrations on the Kaskaskia River changed significantly from upstream to downstream ($F=167.61$, $p<0.0001$) Figure 3-8. Upstream from Lake Shelbyville, which is formed by a dam on the Kaskaskia River, mean nitrate concentrations on the Kaskaskia River were 7.2 mg/L near Allenville; 7.4 mg/L near Cooks Mill; and 7.8 mg/L near Hayes. The tributaries to Lake Shelbyville also exhibited high mean concentrations of nitrates: West Okaw River, 9.3 mg/L (OT 01); Jonathon Creek, 7.7 mg/L (OU 01); and Asa Creek 8.7 mg/L (OZZT01). Mean nitrate concentrations on the Kaskaskia River immediately below Lake Shelbyville (O 11) were 4.1 mg/L. Further downstream on the Kaskaskia River below Lake Carlyle (stations O 30, O 20, and O 07) mean nitrate concentrations were approximately 1.0 mg/L (Figure 3-8). Mean nitrate concentrations at the remaining tributary stations in the Kaskaskia River basin were less than 1.8 mg/L with the exception of Richland Creek, 4.6 mg/L (OC 04). Kelly et al. (1989) noted that one factor in the change of nitrate concentrations on the Kaskaskia River may have been due to a change from two physiographic regions: the

Figure 3-7. Mean total nitrate+nitrite concentrations (mg/L) on the Illinois River and the farthest downstream monitoring station on major tributaries. Illinois EPA AWQMN data, October 1980 - September 1996.

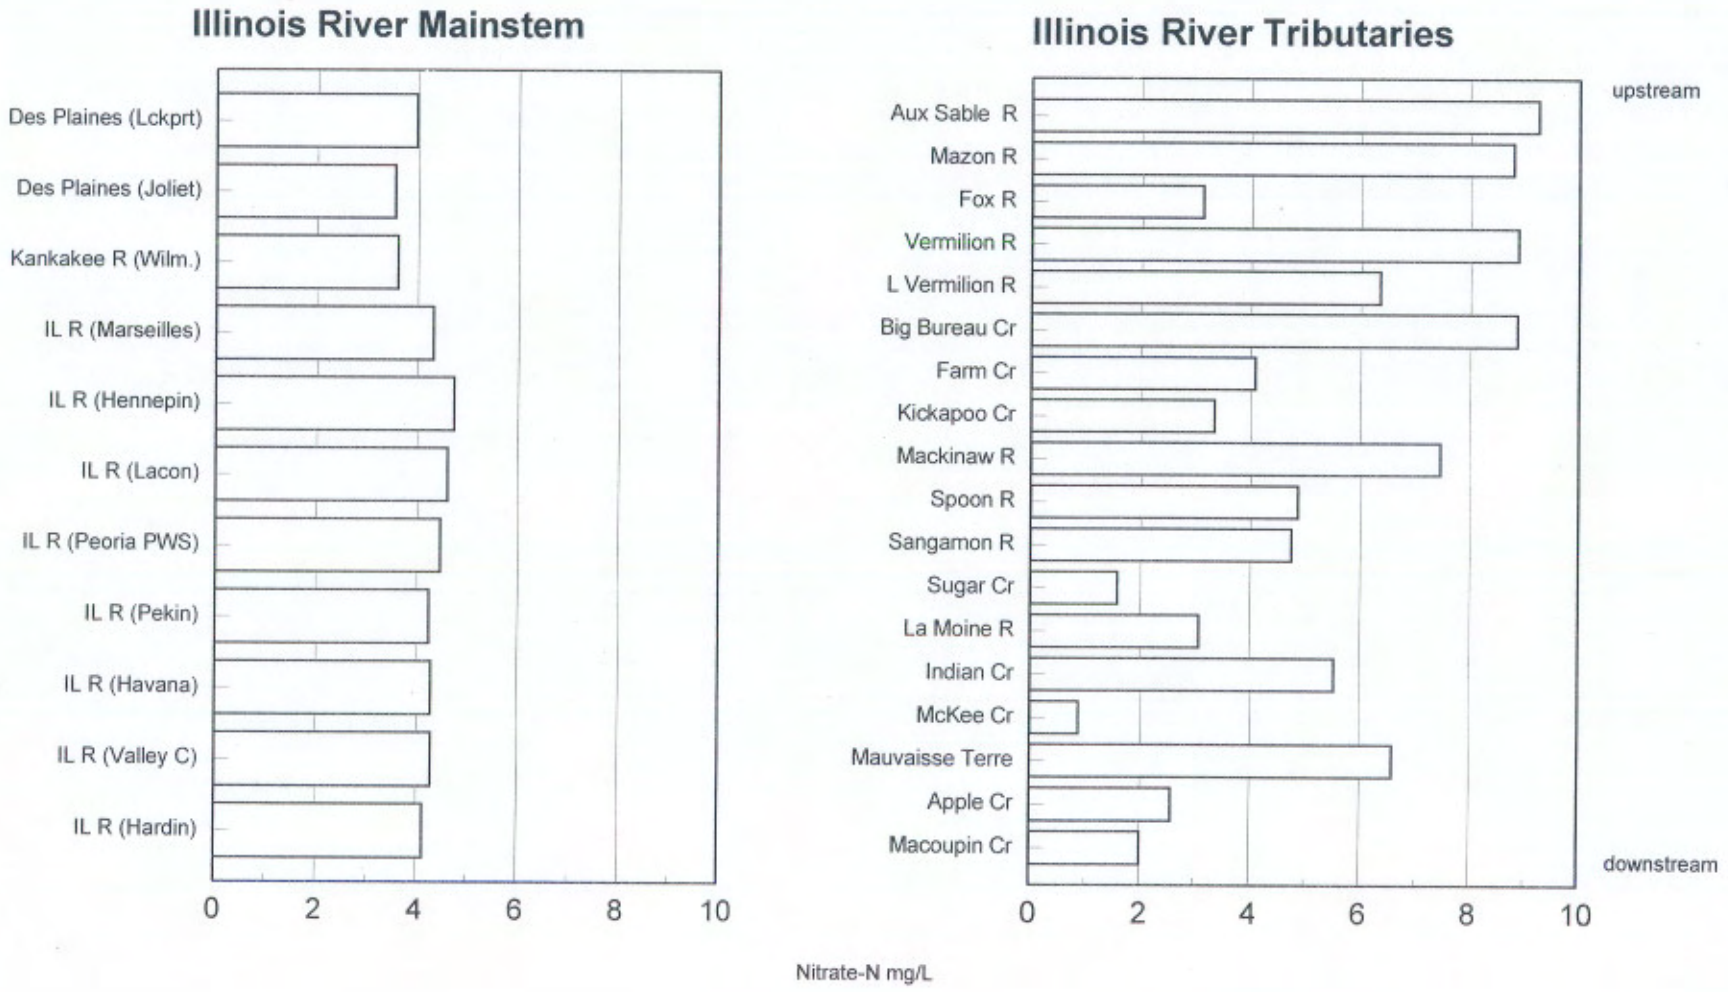

Figure 3-8. Comparisons of nitrates and TKN concentrations from Illinois EPA AWQMN stations on the Kaskaskia River, October 1980 through September 1996.

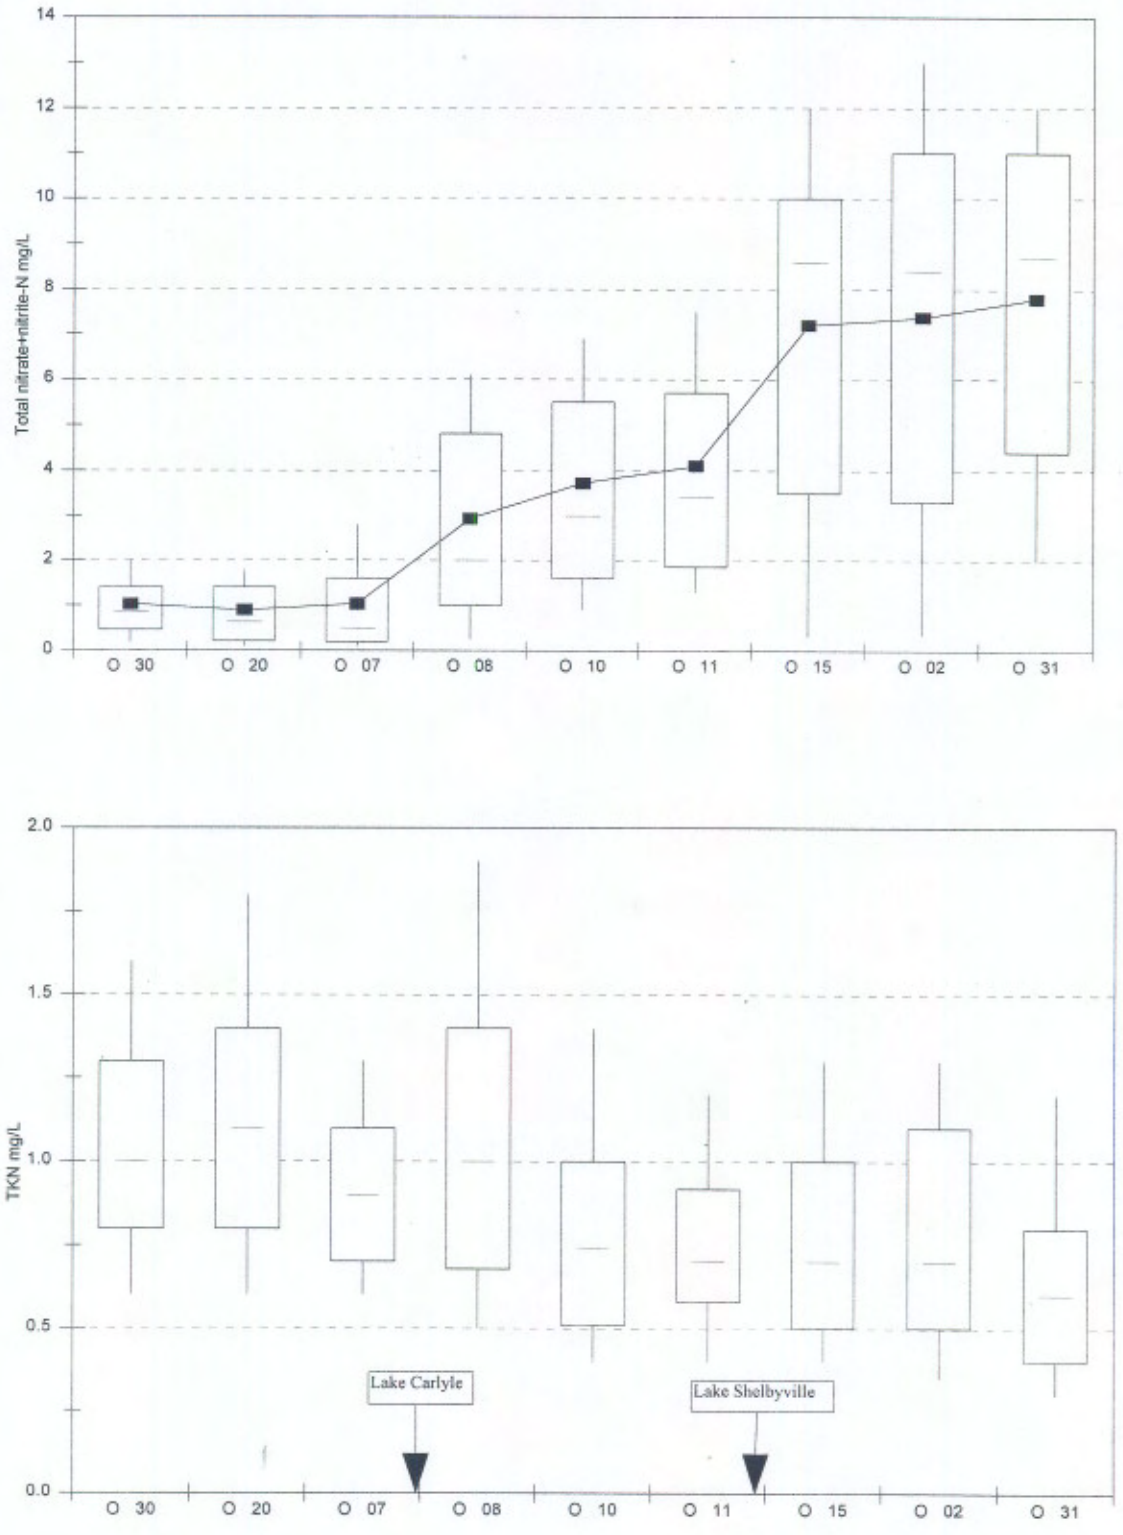

Figure 3-9. Mean total nitrate+nitrite-N concentrations (mg/L) at the farthest downstream monitoring station on tributaries to the Ohio River, the Mississippi River and its tributary stations. Illinois EPA AWQMN data October 1980 - September 1996.

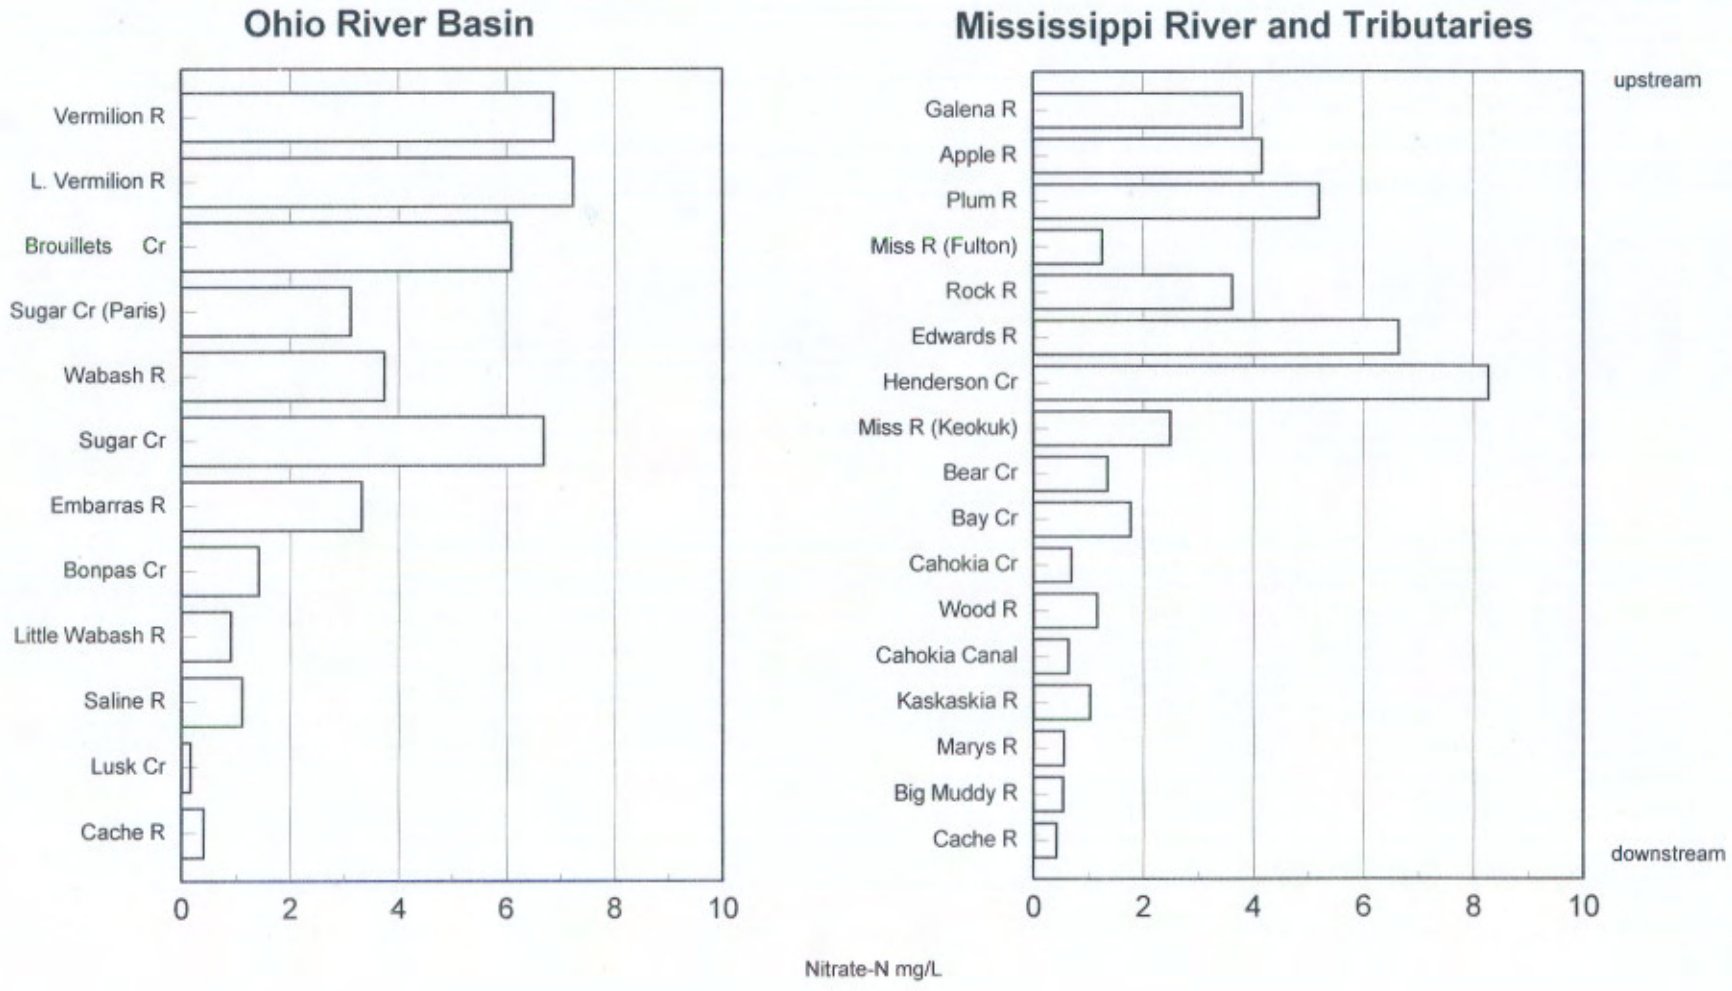

Bloomington Ridged Plain in the upper portions of the watershed above Lake Shelbyville to the Springfield Plain below (see Leighton et al. 1948 for a description of physiographic regions).

Mean nitrate concentrations on direct tributaries to the Mississippi River ranged from 0.54 mg/L on the Big Muddy (N 12) to 8.1 mg/L on Henderson Creek (LD 01). Mean nitrate concentrations were notably higher on the northern tributaries (i.e., means >3.5 mg/L) than the southern tributaries (means <1.8 mg/L). The break occurred between Henderson Creek and Bear Creek (Figure 3-9). On the Mississippi River, nitrate concentrations were higher at Keokuk, 2.5 mg/L (K 04) and Thebes, 1.3 mg/L (I 84) than the farthest upstream station at Fulton, 1.2 mg/L (M 04).

High mean nitrate concentrations were present on two tributaries in the Wabash River basin: Saline Branch, 9.7 mg/L (BPJC06); and the upper Embarras River station near Camargo, 8.0 mg/L (BE 14). Similar to the Kaskaskia River, the Embarras River showed significant variation from upstream to downstream, with decreasing mean nitrate concentrations moving downstream. The Embarras River, like the Kaskaskia River, also flows from the Bloomington Ridged Plain to the Springfield Plain. The North Fork Embarras River had a mean nitrate concentration of 1.1 mg/L. Mean nitrate concentrations were significantly lower in the Cache River, Lusk Creek, Saline River, Little Wabash River and Bonpas Creek drainages (≤1.5 mg/L) than the Embarras River near Billet, BE 01 (≥3.3 mg/L), or Vermilion River (≥6.2 mg/L). Concentrations were also lower on Sugar Creek, 3.1 mg/L (BM 02) than other streams in the area probably due to the effects of the twin lakes at Paris (Figure 3-9).

Total Nitrogen

Total Kjeldahl nitrogen (TKN), which is a measure of total ammonia-N plus organic nitrogen, was analyzed in 11,751 samples collected between October 1980 and September 1996. TKN was routinely collected from 82 of the 209 stations and the statewide mean was 1.39 mg/L (± 0.0134) Table 3-1. Individual station means of TKN ranged from 0.27 mg/L on Lusk Creek (AK 02) to 5.77 mg/L on the Calumet-Sag Channel (H 01). TKN concentrations were significantly correlated with total ammonia-N ($r = 0.738$, $p < 0.0001$). As with the other forms of nitrogen, mean TKN had statistically significant variability between months and years. There was a general decline over time although not as dramatic as the decline in mean ammonia concentrations. Seasonally, September and December had significantly lower TKN concentrations than the other months (Figure 3-10).

Mean concentrations of total Kjeldahl nitrogen and total nitrate plus nitrite nitrogen were added together to estimate total nitrogen concentrations at 78 stations. Four inactive stations were not included due to limited periods of record: A 06 on the Ohio River, B 07 on the Wabash River and the two Mississippi River stations near Elsah, J 05 and J 83. Measures of total nitrogen were significantly correlated with mean nitrate concentrations ($r = 0.767$, $p < 0.0001$) and to a lesser extent, mean ammonia ($r = 0.2538$, $p < 0.025$) (Figure 3-11).

Ammonia comprised greater than 20 percent of the total nitrogen at nine of the 78 stations (Table 3-3). Seven of these stations were affected by point source discharges and included the Des Plaines River at Joliet (G 23); the Chicago Sanitary and Ship Canal (GI 01 and 02); the Cal-Sag Channel (H 01); the Little Calumet River (HB 42); Middle Fork Saline River (ATG 03) and Casey Fork (NJ 07). Point sources were not a factor on the other two stations where ammonia comprised greater than 20 percent of the total nitrogen: Lusk Creek (AK 02) and South Fork Saline River (ATH 05). On Lusk Creek, the overall mean concentration of total nitrogen was very low: 0.43 mg/L, although ammonia comprised 24.4 percent of the total. Ammonia concentrations on the South Fork Saline river were affected by it's tributary, Sugar Creek (ATHG01) which was impacted by acid mine runoff.

On the four Illinois River stations where TKN data was available, nitrates were the primary form of nitrogen and comprised 70 to 75 percent of the total nitrogen. Ammonia comprised 3 to 5 percent of the total nitrogen at the downstream stations at Peoria (D 30) Pekin (D 05) and Valley City (D 32) but was slightly higher, 10.4 percent, near Marseilles (D 23).

On the Mississippi River, mean total nitrogen concentrations were higher at Thebes, 3.5 mg/L and Keokuk, 3.7 mg/L (K 04) than at Fulton, 2.5 mg/L (M 04) due primarily to the higher concentrations of nitrates. Nitrates comprised 62 percent of the total nitrogen on the Mississippi River at Thebes, 67 percent of the total nitrogen at Keokuk (K 04) and 50 percent of the total nitrogen at Fulton (M 04).

"Organic" nitrogen (nitrogen that was neither nitrate or ammonia) comprised greater than 50 percent of the nitrogen at stations located primarily in southern Illinois. This included the North Fork Saline River (ATF 04); South Fork Saline River (ATH 05); the Little Wabash (C 23); the Big Muddy River (N 08, N 10, N 12), and its tributaries Cedar Creek (NA 01), Kinkaid Creek (NB 01), Crab Orchard Creek (ND 02) and Rayse Creek (NK 01); the Kaskaskia River at Okawville (O 20) and its tributaries East Fork Kaskaskia (OK 01), North Fork Kaskaskia (OKA 01) and Hickory Creek (ON 01) Table 3-3.

Table 3-3. Breakdown of mean total nitrogen by station, Illinois EPA AWQMN data.

Station:	Mean Total N mg/L	Composition of total N			Station:	Mean Total N mg/L	Composition of Total N		
		Nitrate	Ammonia	Other			Nitrate	Ammonia	Other

Figure 3-10. Comparison of statewide TKN concentrations from Illinois EPA AWQMN data October 1980 through September 1996.

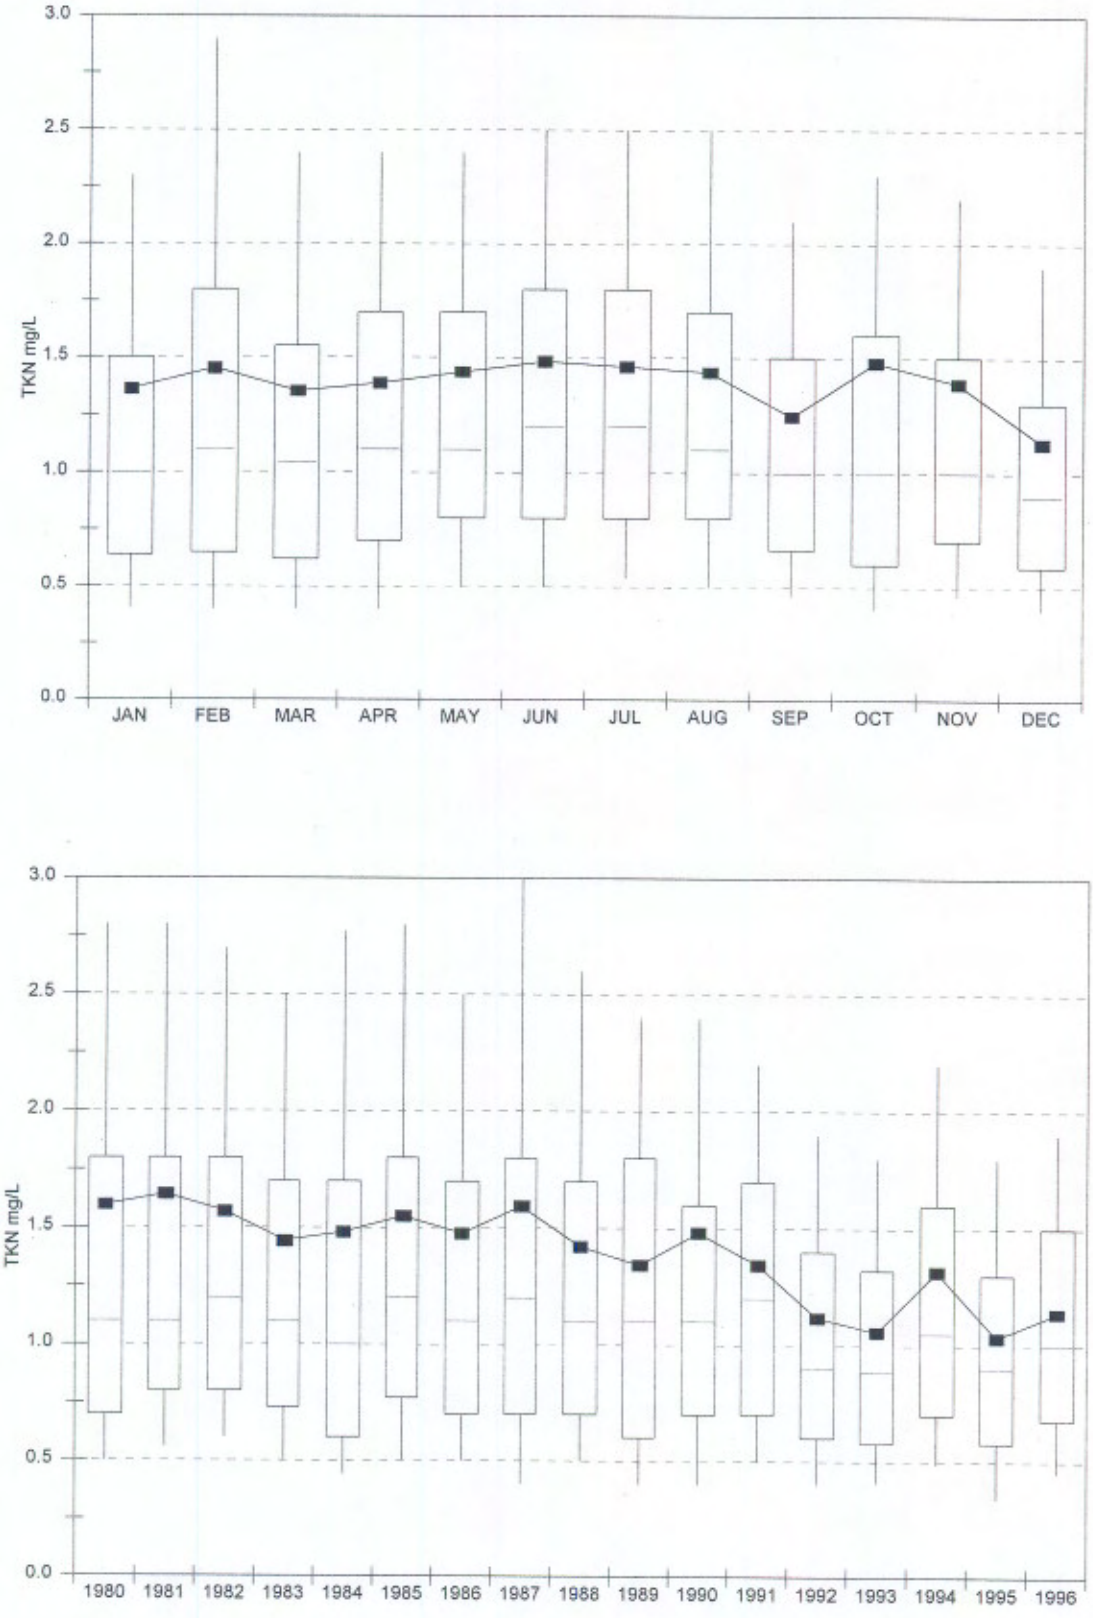

Figure 3-11. Relationship of nitrates and TKN to total nitrogen concentrations from 78 IEPA AWQMN stations, October 1980 - September 1996.

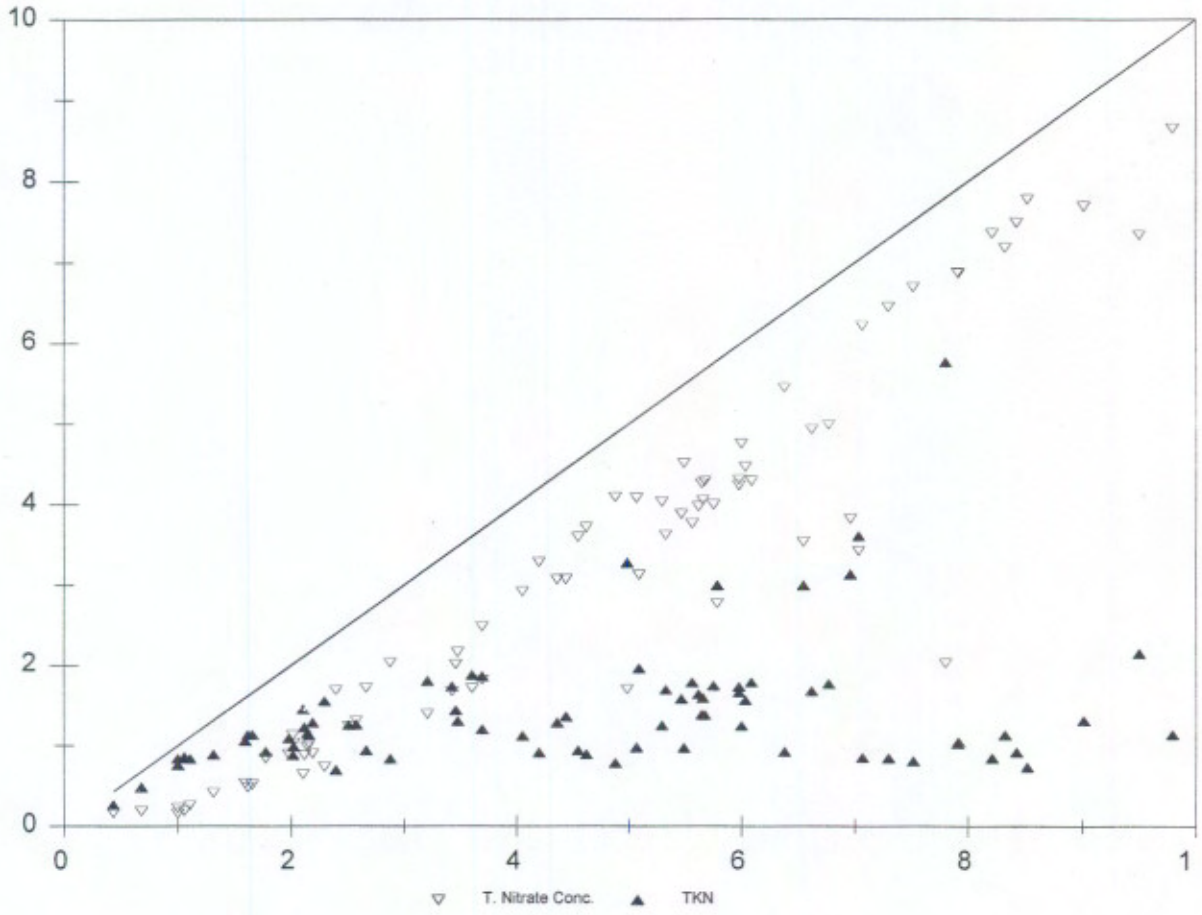

Total Phosphorus

Total phosphorus concentrations were examined from 26,224 samples collected between October 1980 and September 1996. The statewide mean was 0.38 mg/L (± 0.004) Table 3-1. Concentrations were less than ≤0.05 mg/L, the state general use standard for streams above lakes, in 11 percent of the samples. The maximum value, 28 mg/L, was found in one sample from June 1985 on Mauvaisse Terre Creek (DD 04) which is downstream from the city of Jacksonville. Similar to total ammonia-N, mean total phosphorus concentrations were highest in streams below urban areas and their associated wastewater treatment plants (Figure 3-12). Dissolved phosphorus (i.e., after filtration through a 0.45 µm pore diameter filter,) was also evaluated in terms of its relationship to total phosphorus. There were 24,492 pairs of samples in the data set. Dissolved phosphorus was significantly correlated with total phosphorus ($r = 0.965$, $p < 0.0001$). The statewide mean dissolved phosphorus concentration was 0.25 mg/L (±0.004).

Total phosphorus concentrations had statistically significant variation between both months and years (Table 3-2). Mean concentrations were lowest during April and increased during the late summer and fall months, August - November (Figure 3-13). Highest mean annual concentrations of phosphorus occurred during 1988 and 1989 and lowest concentrations occurred during 1982 and 1993 (Figure 3-13). Total phosphorus concentrations at a number of stations increased during low flow periods due to point source inputs. No overall trend was apparent in the statewide data set.

At individual stations, mean total phosphorus ranged from 0.02 mg/L on Lusk Creek (AK 02) to 2.68 mg/L on Mauvaisse Terre Creek (DD 04). Of the 203 active stations, 11 had mean total phosphorus concentrations less than 0.10 mg/L; 61 stations had mean concentrations between 0.10 and 0.20 mg/L; 62 stations had mean concentrations between 0.21 and 0.30 mg/L; and 23 stations had mean concentrations between 0.31 and 0.40 mg/L. Streams which had the highest mean concentrations of total phosphorus (i.e., Mauvaisse Terre Creek) were generally downstream from urban areas or wastewater treatment plants. High mean total phosphorus concentrations were present at: Saline Branch, 2.43 mg/L (BPJC06) and Sugar Creek, 1.13 mg/L (BF 01) in the Wabash River drainage; Canteen Creek, 2.25 mg/L (JNA 01); Sangamon River, 1.66 mg/L (E 05) and 1.18 mg/L (E 16); in the Kaskaskia River basin, Richland Creek, 1.28 mg/L (OC 04); Silver Creek 1.02 mg/L (OD 06); and Sugar Creek, 0.99 mg/L (OH 01). In the Des Plaines River basin: Salt Creek, 1.61 mg/L (GL 09); Du Page River, 1.16 mg/L (GB 10) and 0.98 mg/L (GB 11); West Branch Du Page River, 1.50 mg/L (GBK 09) and 1.29 mg/L (GBK 05); East Branch Du Page River, 1.36 mg/L (GBL 10); Calumet-Sag Channel, 1.19 mg/L (H 01) and Thorn Creek, 2.63 mg/L (HBD 04). Dissolved phosphorus comprised 80 percent or more of the total phosphorus concentrations at 10 of these stations: BPJC06, BF 01, E 05, GB 10, GB 11, GBK 05, GBK 09, GBL 10, GL 09, and HBD 04 (Table 3-4).

In the Rock River basin, mean total phosphorus concentrations ranged from 0.10 mg/L on Kilbuck Creek (PQB 02) to 0.48 mg/L on the Kyte River (PL 03). On the five Rock River stations there was no significant variation in means between stations and mean total phosphorus

Table 3-4. Ratio of dissolved phosphorus to total phosphorus (mg/L). Illinois EPA AWQMN data.

Note this is a corrected copy. The original report table incorrectly indicated the concentrations were mean values, they are median values. MBS. May 2000.

concentrations were approximately 0.30 mg/L.

Mean total phosphorus concentrations at the farthest downstream Des Plaines River station, 0.68 mg/L (G 23) were significantly higher than the Kankakee River near Wilmington 0.12 mg/L (F 01). On the Illinois River, mean total phosphorus concentrations were significantly higher at the farthest upstream station, Marseilles, 0.43 mg/L (D 23) than the other stations ($F=15.61$, $p<0.0001$). Mean total phosphorus concentrations at the other Illinois River stations ranged from 0.31 mg/L near Valley City (D 32) to 0.36 mg/L near Pekin (D 05) (Figure 3-14).

Tributaries to the Illinois River generally had mean total phosphorus concentrations that were less than the statewide mean, 0.38 mg/L. Exceptions to this included Mauvaisse Terre Creek, 2.68 mg/L (DD 04); Big Creek, 0.61 mg/L (DJB 18) downstream from Canton in the Spoon River drainage; Big Bureau Creek, 0.46 mg/L (DQ 03); Sugar Creek in the Sangamon River basin, 0.73 mg/L (EID 04) downstream of Bloomington/Normal and the entire main stem Sangamon River downstream of Decatur to the mouth. Mean concentrations of total phosphorus on the Sangamon River downstream from Lake Decatur ranged from 0.41 mg/L near Oakford (E 25) to 1.66 mg/L near Niantic (E 05).

On the Kaskaskia River mean total phosphorus concentrations were lowest, 0.06 mg/L, immediately downstream from the Lake Shelbyville dam (O 11). Concentrations at the other eight main stem stations ranged from 0.14 mg/L near Cowden (O 10) to 0.30 mg/L near Okawville (O 20). Like nitrates, total phosphorus concentrations dropped significantly downstream of Lake Shelbyville and Lake Carlyle, however, unlike nitrates, total phosphorus concentrations increased overall in the lower portion of the watershed (Figure 3-15).

Mean total phosphorus concentrations on direct tributaries to the Mississippi River ranged from 0.21 mg/L on the Big Muddy River and 0.23 mg/L on the Apple River (MN 03) to 2.25 mg/L on Canteen Creek (JNA 01). Mean total phosphorus concentrations were also elevated on Henderson Creek, 0.76 (LD 02) and Harding Ditch, 0.63 mg/L (JMAC02). On the Mississippi River, mean total phosphorus concentrations were variable with a slight increasing concentration moving downstream. At Fulton (M 04), the mean total phosphorus concentration was 0.18 mg/L, at Keokuk, 0.21 mg/L (K 04) and at Thebes, 0.29 mg/L (I 84). The increase in phosphorus concentrations on the Mississippi River probably reflected the increasing suspended sediment concentrations from upstream to downstream (Figure 3-16).

In the Ohio River drainage, mean total phosphorus concentrations were highest on Sugar Creek near Palestine, 1.13 mg/L (BF 01) and Saline Branch near Mayview, 2.43 mg/L (BPJC06). Mean total phosphorus concentrations on Salt Fork Vermilion River near Oakwood, 0.86 mg/L (BPJ 03) were affected by phosphorus levels in Saline Branch. Other stations in the Ohio River basin had means that were less than 0.41 mg/L with the exception of Sugar Creek (ATHG01) near Stonefort (0.65 mg/L) Figure 3-16.

Total Suspended Solids

Total suspended solids (TSS) concentrations were examined from 29,641 samples collected between October 1980 and September 1996. The statewide mean was 80.6 mg/L (± 1.32) Table 3-1. The statewide mean was skewed due to a relatively small portion of values (0.76 percent) which equaled or exceeded 1000 mg/L. Half of the samples, or the median value, had TSS concentrations which were equal to or less than 36 mg/L. The statewide TSS mean value (80.6 mg/L) was greater than the concentration in 77.5 percent of the samples. TSS concentrations ranged from 1.0 mg/L in one percent of the samples to a maximum of 12,300 mg/L. TSS concentrations showed significant variations between months (Table 3-2). Mean concentrations rose steadily from January to June and declined sharply into August and the fall months (Figure 3-17). Changes in annual means were also significant (Table 3-2). The highest mean concentrations of TSS occurred during 1981 and the lowest concentrations occurred during 1987 through 1989 (Figure 3-17).

At individual stations mean TSS concentrations ranged from 9.1 mg/L on Kinkaid Creek (NB 01), downstream from Lake Kinkaid in the Big Muddy River basin, to 308 mg/L on the Spoon River (DJ 08) a tributary to the Illinois River. Concentrations were lowest at stations located downstream from lakes such as on the Kaskaskia River, 10.4 mg/L below Lake Shelbyville (O 11); Crab Orchard Creek, 13.1 mg/L below Crab Orchard Lake (ND 01); the Sangamon River, 26.9 mg/L downstream from Lake Decatur (E 06); Clear Creek, 19.2 mg/L downstream from Lake Sangchris (EOD 01); and the Big Muddy River below Rend Lake (N 10) 14.7 mg/L. Mean TSS concentrations were also low on the Chicago Sanitary and Ship Canal,17.0 mg/L (GI 02) and downstream in the Des Plaines River, 27.3 mg/L (G 23). Flows at these two stations are dominated by municipal wastewater treatment plant discharges and to a lesser extent, the Lake Michigan diversion. In most of the remaining basins, mean TSS concentrations tended to be highest at the farthest downstream station within a basin. This was due in part to the fact that particles which are deposited in the river bed from upstream areas become resuspended in the water column during high flows. In addition, streams in west central Illinois had higher mean TSS concentrations possibly due to more erodible soils (Figure 3-18).

In the Rock River basin, mean TSS concentrations ranged from 15.1 mg/L on the Kishwaukee River (PQ 10) to 93.8 mg/L on the Rock River (P 04). Mean TSS concentrations were significantly higher on the Pecatonica River, 88.5 mg/L (PW 01) than the other tributaries in the basin. On the Rock River, mean TSS concentrations ranged from 52.6 (P 14) to 93.8 mg/L and may have been effected by dams on the stream.

Total suspended solids was the only parameter reviewed that had lower mean concentrations on the Des Plaines River, 27.3 mg/L (G 23) than the Kankakee River near Wilmington (F 01), 45.3 mg/L. Mean TSS concentrations on the Illinois River showed a significant increase from upstream to downstream (Figure 3-19). Concentrations at Hardin, near the mouth, were 149 mg/L (D 01) and at Valley City (D 32) and were significantly higher than the other stations ($F=29.12$, $p<0.0001$). TSS concentrations on the upper end of the Illinois

River near Marseilles (D 23) were 43 mg/L. Mean TSS concentrations on tributaries to the Illinois River ranged from 34.4 mg/L on both the Mazon River (DV 04) and Aux Sable Creek (DW 01) to 308 mg/L on the Spoon River (DJ 08). Mean TSS concentrations exceeded 100 mg/L in all of the central and western tributaries to the Illinois River, but were less than 100 mg/L in the northern tributaries (Fox River, Vermilion River, Big Bureau Creek). The lower stations on Kickapoo Creek (DL 01), Mackinaw River (DK 12), Spoon River (DJ 08), LaMoine River (DG 01), Indian Creek (DF 04), McKee Creek (DE 01) and Macoupin Creek (DA 06) had mean TSS concentrations which exceeded 200 mg/L.

On the Kaskaskia River mean total suspended solids concentrations were lowest immediately downstream from the Lake Shelbyville dam, 10.4 mg/L (O 11). Upstream from Lake Shelbyville, mean TSS concentrations ranged between 51.7 and 65.3 mg/L. Unlike nitrates and to an extent total phosphorus, mean TSS concentrations were lower upstream of Lake Shelbyville than the downstream stations. Mean TSS concentrations dropped again below Lake Carlyle and the highest concentration was near Vandalia, 127.2 mg/L (O 08) Figure 3-15. Mean TSS concentrations on tributaries to the Kaskaskia River were highest on Silver Creek ranging between 134.8 at OD 07 to 152.2 mg/L at OD 06.

Mean total suspended solids concentrations on the small direct tributaries to the Mississippi River ranged from 37.1 mg/L on the Big Muddy River (N 12) to 224.5 mg/L on Bear Creek near Marcelline (KI 02). Mean TSS concentrations on Bear Creek, Bay Creek (KCA 01), Edwards River (LF 01), Henderson Creek (LD 02), Cahokia Creek (JQ 05) and Cahokia Canal (JQ 02) exceeded 155 mg/L (Figure 3-20). On the Mississippi River, mean TSS concentrations increased from upstream to downstream. At Fulton (M 04), mean TSS concentrations were 49.7 mg/L, at Keokuk, 71.8 mg/L (K 04) and at Thebes, 196.5 mg/L (I 84).

In the Ohio River basin, mean total suspended solids concentrations ranged from 9.5 mg/L on Lusk Creek (AK 02) to 131.2 on the Embarras River near Billet (BE 01). With the exception of the Little Vermilion River (44.4 mg/L), mean TSS concentrations were between 50 to 100 mg/L (Figure 3-20).

Figure 3-17. Comparison of statewide concentrations of TSS from Illinois EPA AWQMN data October 1980 through September 1996.

4. EVALUATION OF BASELINE LOADS

Baseline loads were calculated for inorganic nitrogen, which was based on adding total ammonia-N plus total nitrate+nitrite-N concentrations, total nitrogen, based on adding total nitrates+nitrite-N and TKN, total and dissolved phosphorus, and total suspended solids. As stated in the introduction, baseline loads were based on the mean load for a station over the 16 year period of record. Yields were based on the baseline load divided by drainage area. Because TKN was not universally available at all the stations, data on total nitrogen baseline loads was also limited. Although the initial period of record (October 1980 through September 1996) for the baseline loads was the same as the concentration analysis, the ending date was not consistent due to two factors. First, over time the USGS had reduced the number of active stream gaging stations that they maintain and secondly the USGS discontinued providing the Illinois EPA with estimations of flows at ungaged stations in 1992. The period of flow record available for each station is listed in Appendix Table A-1. Stations where loads were based on less than a 16 year period (October 1980 through September 1996) are marked in the report figures and tables with an asterisk (*). Of the 209 stations, 98 stations had 16 years of flow data, 57 stations had between 10 and 15 years of flow data associated with the water quality samples and the remaining 54 stations had no or insufficient flow data to be included in the analysis. This resulted in a minimum sample size of 46, for total phosphorus on Pond Creek (NG 02) near Frankfort, Illinois. Other methods utilized for calculating baseline loads include multiplying the mean concentration of a constituent by the mean stream flow (USEPA, 1992), and extrapolation of loadings from monitored tributaries based on regression analysis to adjacent streams (Robertson, 1997).

The accuracy of loading estimates is dependent on several factors: the frequency of sampling, the flow regime of the stream, and the relation (if any) between flow and constituent concentrations. Recognizing the limitations of the data is important for the proper interpretation of the information. Traditionally, loading studies in streams have been done on suspended sediment (Simmons, 1976) and are generally based on daily samples (Holmes, 1997). Water quality sampling methods used by the Illinois EPA, which were developed and utilized by the USGS, were intended to provide a consistent sample of suspended particles in the water column at a variety of flow conditions. Although the USGS has collected daily samples at a number of stations, the data set does not exist for continuous periods of record on a statewide scale. The Illinois State Water Survey has also maintained a stream sediment sampling program with weekly samples since 1981. This program initially consisted of 50 stations but was reduced to 31 stations after just one year and as of 1994 consisted of 15 stations (Allgire and Demissie, 1995). Collections of daily or even weekly stream nutrient data is even more limited. This usually occurs when a specific reach of a stream is monitored by a municipality for either a public water supply (Lucey and Goolsby, 1993) or to track the effects of treated wastewater on a receiving stream. Data of this type is usually not readily available. Since the goal of this report was to estimate baseline loadings, use of the AWQMN facilitated a more appropriate portrayal of loadings at the state level. However, localized studies and monitoring programs, such as the

ISWS stream sediment program, provide more detailed and accurate information on loads from specific areas (Keefer and Demissie, 1996, and Demissie and Keefer, 1996).

Results

Summaries of STORET load data, in pounds per day by station along with the number of samples, are presented in Appendix C. Baseline loads were then converted to $Kg \cdot day^{-1}$, and baseline yields to $Kg \cdot Ha^{-1} \cdot Yr^{-1}$, and are listed by station in Tables 4-1 and 4-2 respectively. As with concentrations, the discussion is by parameter and watershed. Inorganic and total nitrogen loads are discussed together as are total and dissolved phosphorus. Loads, which reflect concentration multiplied by flow, and yields, which reflect loads divided by area, are also discussed by watershed.

Nitrogen

On the five Rock River stations, baseline loads of inorganic nitrogen ranged from 59,363 $Kg \cdot day^{-1}$ at the farthest upstream station near Rockton (P 15) to 82,690 $Kg \cdot day^{-1}$ at the farthest downstream station near Joslin (P 04). The only other stations in Illinois (excluding stations on the border streams: Mississippi River, Ohio River and Wabash River) which exceeded the baseline loads of inorganic nitrogen on the Rock River were the farthest downstream station on the Kankakee River (F 01) and the eight stations on the Illinois River. Yields of inorganic nitrogen on the Rock River were similar at all five stations and ranged from11 to13 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$. Baseline loads of inorganic nitrogen were lower on the tributaries to the Rock River, due primarily to lower flow volumes, and ranged from 1,678 $Kg \cdot day^{-1}$ on the Kishwaukee River near Garden Prairie to 18,859 $Kg \cdot day^{-1}$on the Pecatonica River at Harrison. However, yields of inorganic nitrogen on the tributaries to the Rock River were significantly higher than the Rock River. Yields of inorganic nitrogen were highest on Elkhorn Creek near Penrose (28.8 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$); Kilbuck Creek near Rockford (25.6 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$); and the South Branch Kishwaukee River near Kirkland (30.4 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$). Yields of inorganic nitrogen on the Green River (PB) and Pecatonica River (PW)were similar to each other and ranged from 14 to 16, $Kg \cdot Ha^{-1} \cdot Yr^{-1}$ (Figure 4-1).

Baseline loads of total nitrogen were available from the five Rock River mainstem stations and ranged from 76,560 $Kg \cdot day^{-1}$ (P 15) to 115,116 $Kg \cdot day^{-1}$ (P 04). The only other station in the Rock River basin where total nitrogen loadings were available was on the Green River near Geneseo (PB 04): 14,450 $Kg \cdot day^{-1}$ (Figure 4-2). Nitrogen in the form of nitrates comprised 68 to 74 percent of the baseline total nitrogen load from these six stations(Figure 4-3).

Baseline loads of inorganic nitrogen on the Illinois River ranged from 133,655 $Kg \cdot day^{-1}$ at the farthest upstream station near Marseilles (D 23) to 383,580 $Kg \cdot day^{-1}$ at the farthest downstream station near Hardin (D 01). On the two tributaries which form the Illinois River,

* indicates loads based on less than 16 years of flow data

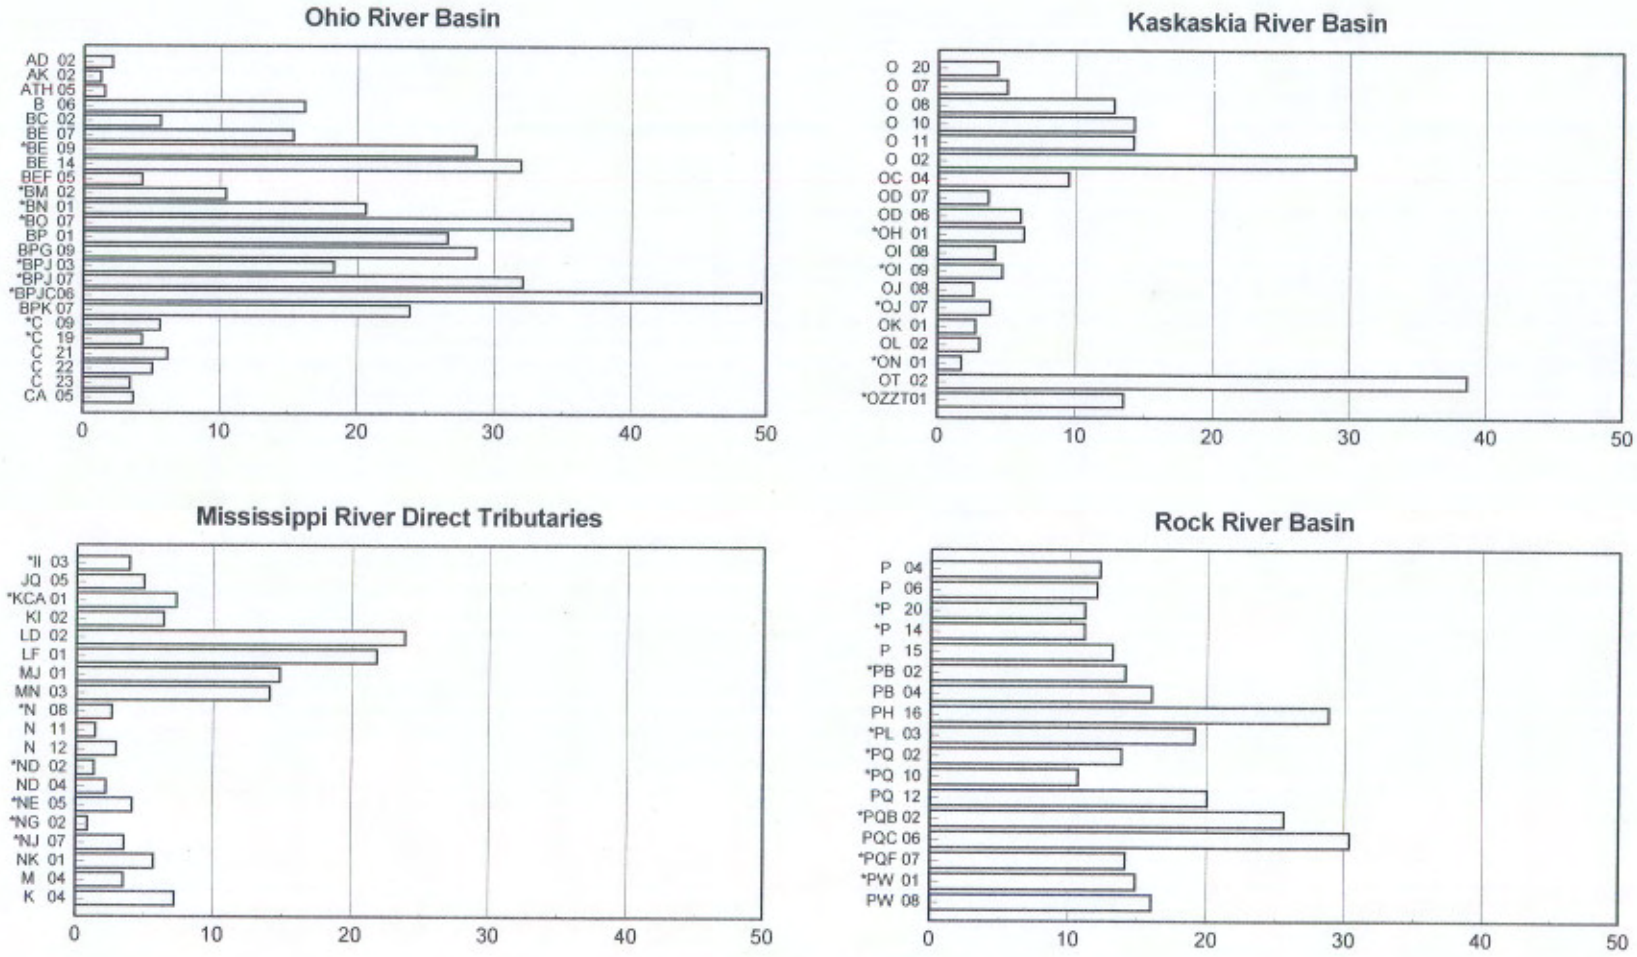
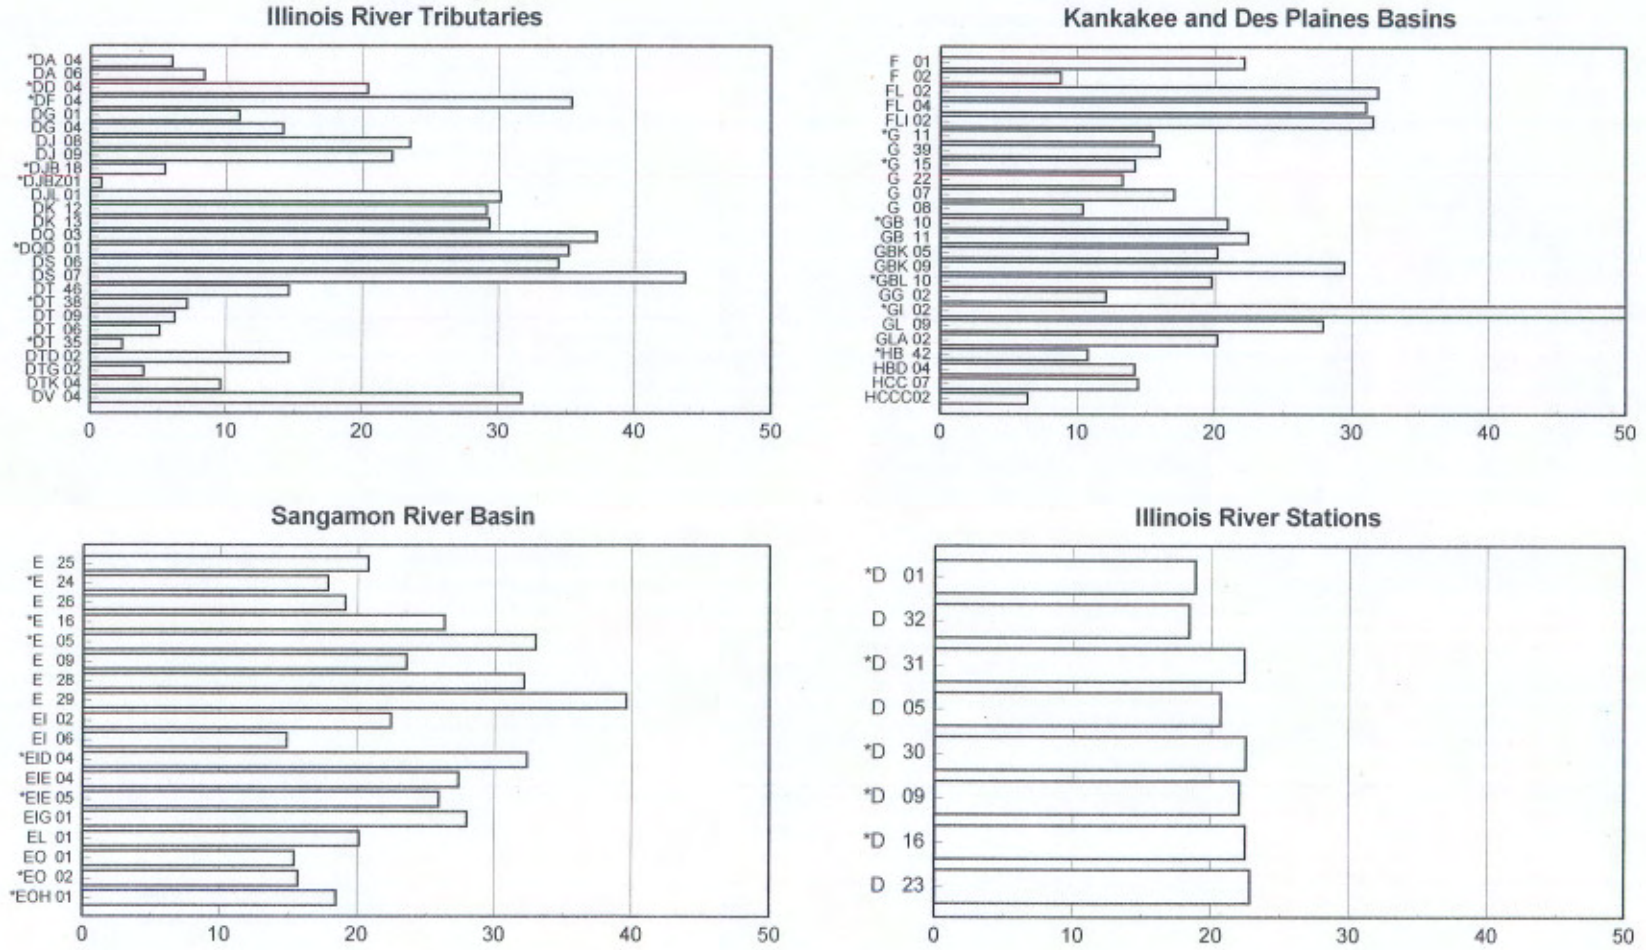
Figure 4-1. Comparisons of baseline yields of inorganic-N (Kg/Hectare/Year) Illinois EPA AWQMN data October 1980 - September 1996.



* indicates less than 16 years of flow data

Figure 4-1 (cont) . Comparisons of baseline yields of inorganic-N(Kg/Hectare/Year).
Illinois EPA AWQMN data October 1980 - September 1996.
The value for the Sanitary and Ship Canal (GI 02) is 87.1 Kg/Ha/Yr.



* indicates less than 16 years of flow data

baseline loads of inorganic nitrogen were 80,803 $Kg \cdot day^{-1}$ on the Kankakee River near Wilmington (F 01) and estimated to be, based on combining the three farthest downstream stations on the Des Plaines River, Salt Creek and the Chicago Sanitary and Ship Canal (G 11, GB 11, and GI 02 respectively) 59,000 $Kg \cdot day^{-1}$ from the Des Plaines River basin. Baseline loadings on the Chicago Sanitary and Ship Canal (GI 02) at 45,705 $Kg \cdot day^{-1}$ made up the bulk of the inorganic nitrogen load from the Des Plaines River basin. Baseline loads on the Iroquois River, a tributary to the Kankakee River, were 47,289 $Kg \cdot day^{-1}$ and comprised the majority of the loading of inorganic nitrogen to the Kankakee River. The Mazon River (DV 04), which is also upstream from the station on the Illinois River at Marseilles, had a baseline loading of 10,243 $Kg \cdot day^{-1}$.

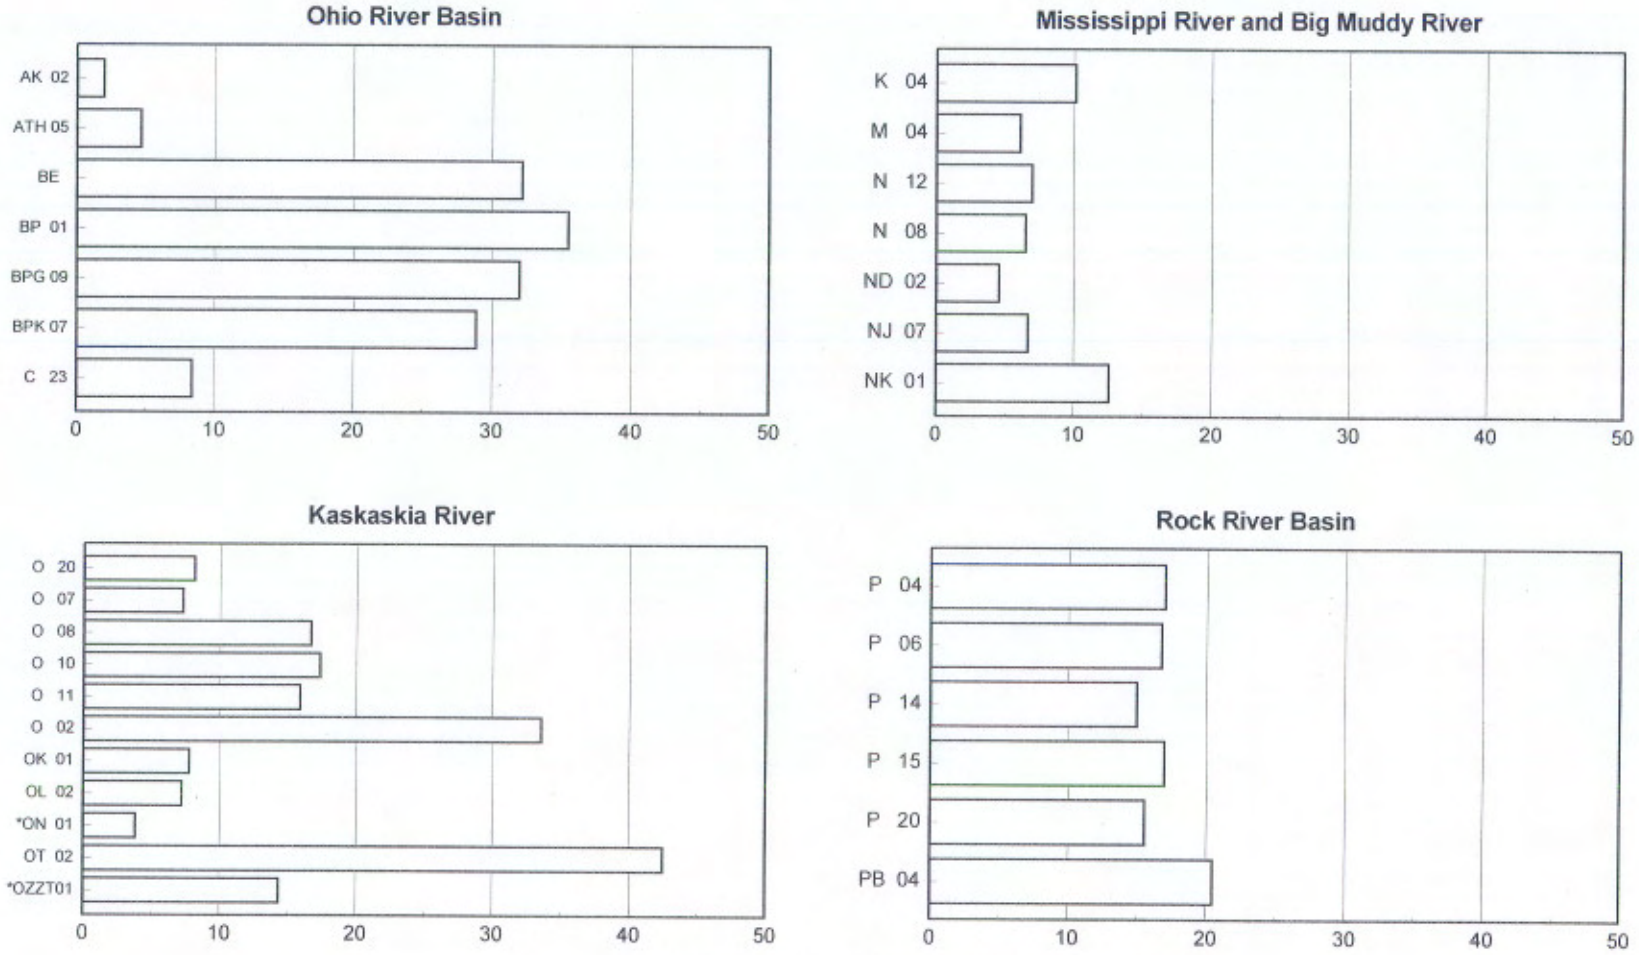
Yields of inorganic nitrogen on the Illinois River ranged from 18.9 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$ near Hardin (D 01) to 22.8 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$ at Marseilles (D 23). Yields of inorganic nitrogen from the Kankakee River were 22.1 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$ at the farthest downstream station near Wilmington (F 01). Yields were much lower on the upper Kankakee River near Momence (F 02), 8.76 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$ indicating that the majority of inorganic nitrogen in the Kankakee River was coming from the Iroquois River. Both monitoring stations on the Iroquois River had yields of inorganic nitrogen that were greater than 31 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$ (Figure 4-1).

Baseline loads of inorganic nitrogen to the Illinois River from its major tributaries ranged from 2,112 $Kg \cdot day^{-1}$ on Mauvaisse Terre Creek (DD 04) to 74,986 $Kg \cdot day^{-1}$ on the Sangamon River near Oakford (E 25). Baseline loads of inorganic nitrogen were greater than 22,000 $Kg \cdot day^{-1}$ at the farthest downstream stations on the Spoon River, Mackinaw River, Vermilion River and Fox River (Table 4-8). Yields of inorganic nitrogen ranged from 8.41 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$ on Macoupin Creek (DA 06) to 43.71 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$ on the Vermilion River (DS 07). Yields on Big Bureau Creek, 37.19 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$, and Indian Creek (DF 04), 35.39 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$ were also considered high (Figure 4-2).

Baseline loads of total nitrogen were available from 26 of the 94 stations in the Illinois River basin. Baseline loads of total nitrogen on the Illinois River ranged from 163,530 $Kg \cdot day^{-1}$ at Marseilles (D 23) to 426,090 $Kg \cdot day^{-1}$ at Valley City (D 32). Baseline loads from the farthest downstream station on tributaries to the Illinois River were 100,014 $Kg \cdot day^{-1}$ for the Kankakee River; 40,907 $Kg \cdot day^{-1}$ for the Fox River (DT 46); 90,1834 $Kg \cdot day^{-1}$ on the Sangamon River (E 25); and 16,024 $Kg \cdot day^{-1}$ from the La Moine River (DG 01). Yields of total nitrogen on the Illinois River ranged from 22.6 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$ at Valley City (D 32) to 27.9 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$ at Marseilles (D 23). Yields from the farthest downstream station on tributaries were 21.8 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$ on the Fox River; 25 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$ on the Sangamon River ; and 17.5 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$ on the La Moine River (Figure 4-2).

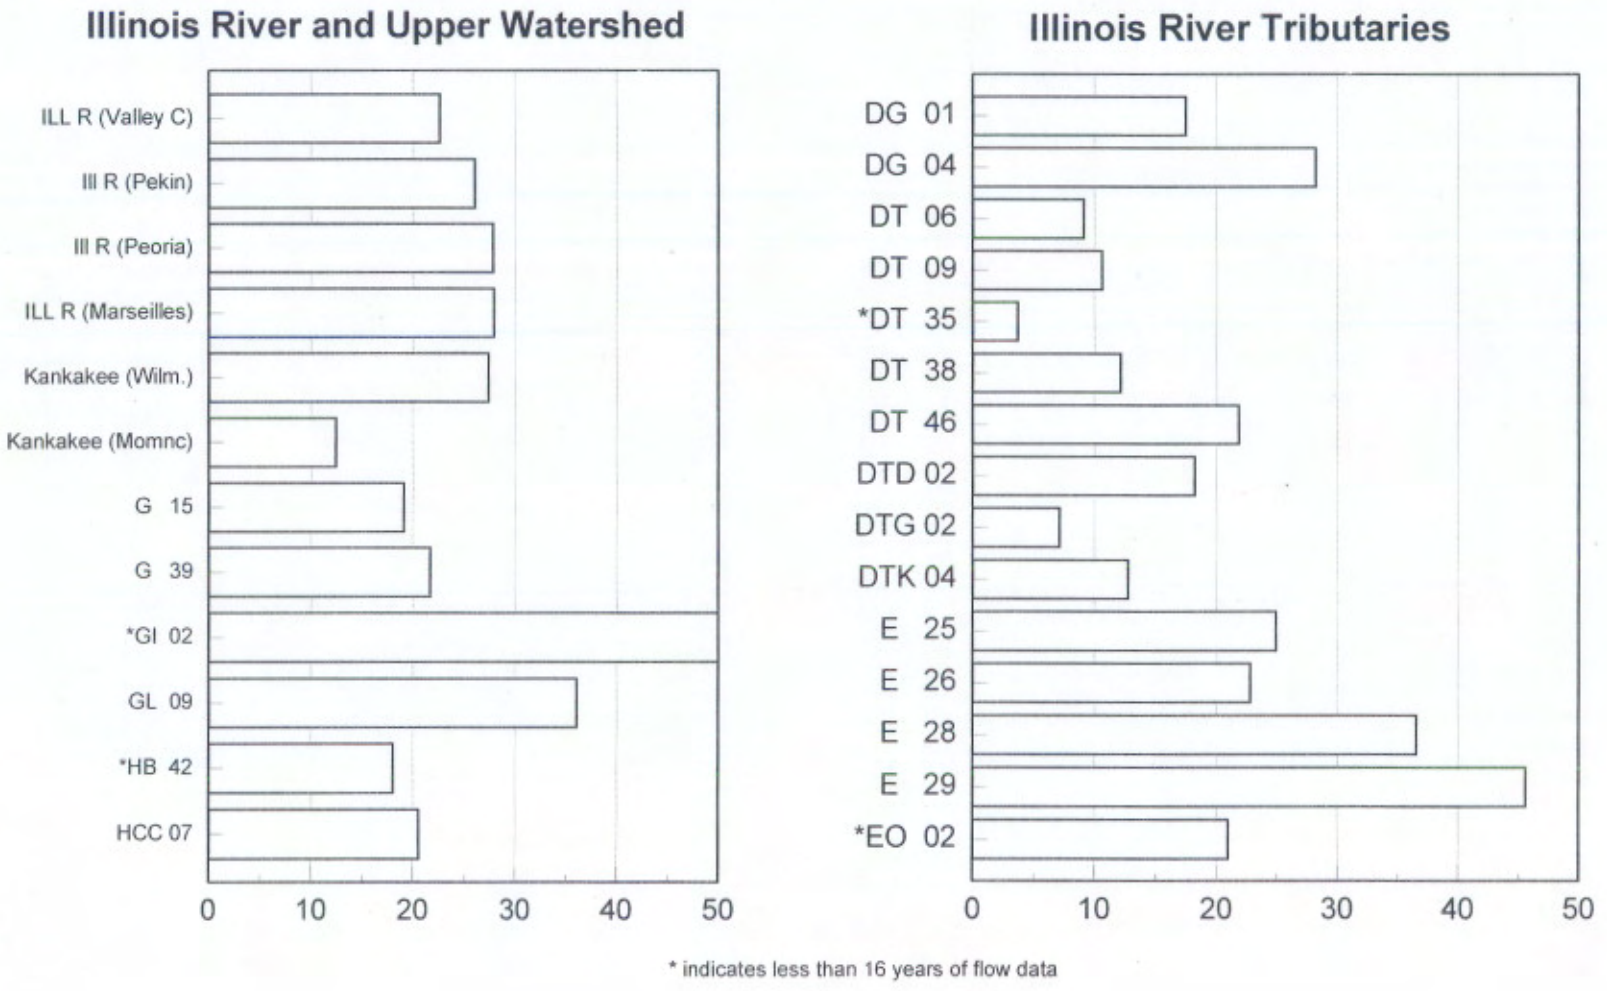
Nitrogen in the form of ammonia comprised between 5 and 10 percent of the total nitrogen baseline loads on the Illinois River at Marseilles (D 23), the Des Plaines River (G 15 and G 39), Salt Creek (GL 09), North Branch Chicago River (HCC 07) and the Fox River near Elgin (DT 09). On the Little Calumet River (HB 42), ammonia comprised 18.3 percent of the

Figure 4-2. Comparisons of baseline yields of total nitrogen (TKN + nitrates) (Kg/Hectare/Year). Illinois EPA AWQMN Data 1980-1996.



* indicates less than 16 years of flow data

Figure 4-2 (cont). Comparisons of baseline yields of total nitrogen (TKN + nitrates) Kg/Hectare/Year. Illinois EPA AWQMN Data 1980-1996.



* indicates less than 16 years of flow data

baseline total nitrogen load. Ammonia comprised less than 5 percent of the total nitrogen load at the remaining Illinois River basin stations. Nitrogen in the form of nitrates comprised approximately 76 percent of the baseline total nitrogen load on the Illinois River. On the mainstem Sangamon River, nitrates comprised approximately 84 percent of the baseline total nitrogen loading. On the La Moine River and Fox River, nitrates comprised approximately 53 and 58 percent of the baseline total nitrogen loading respectively (Figure 4-3).

On the six Kaskaskia River stations, baseline loads of inorganic nitrogen ranged from 9,638 Kg $\cdot day^{-1}$ downstream from the Lake Carlyle dam (O 07) to 17,597 Kg $\cdot day^{-1}$ upstream from Lake Carlyle (O 08). Yields of inorganic nitrogen ranged from 4.3 to 5.0 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$ downstream of Lake Carlyle (O 20 and O 07) but were significantly higher upstream of Lake Shelbyville, 30.4 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$, near Cooks Mill (O 02). Yields on tributaries upstream of Lake Shelbyville were also significantly higher than the other tributaries in the watershed. Yields of inorganic nitrogen on the West Okaw River (OT 02) and Asa Creek (OZZT01)were 38.6 and 13.5 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$ respectively (Figure 4-1).

Baseline loads of total nitrogen were available from 11 of the 26 AWQMN stations in the Kaskaskia River basin. On the Kaskaskia River loads ranged from 11,249 Kg $\cdot day^{-1}$ near Cooks Mill (O 02) to 25,218 Kg $\cdot day^{-1}$ at Okawville (O 20) Figure 4-2. Nitrogen in the form of nitrates comprised 80 percent or more of this load on the stations upstream from Lake Shelbyville and two main stem sites between Lake Shelbyville and Lake Carlyle (O 10 and O 08). Nitrogen in the form of organic nitrogen comprised 45 percent or more of the baseline nitrogen loads on the lower Kaskaskia River (O 20) East Fork Kaskaskia River, Hurricane Creek and Hickory Creek (Figure 4-3).

On the smaller direct tributaries to the Mississippi River, baseline loads of inorganic nitrogen ranged from 309 $Kg \cdot day^{-1}$ on Mary's River (II 03) to 7,319 $Kg \cdot day^{-1}$ on Henderson Creek (LD 02). Yields of inorganic nitrogen ranged from 3.9 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$ on Mary's River to 14.8 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$ on the Plum River (MJ 01). Yields on the Mississippi River at Fulton (M 04) and Keokuk, Iowa (K 04) were 3.5 and 7.3 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$ respectively. Out of the 19 stations, baseline loads of total nitrogen were limited to five stations in the Big Muddy River basin and the two Mississippi River stations.

In the Ohio River basin, baseline loads of inorganic nitrogen were available from 24 stations and ranged from 37 $Kg \cdot day^{-1}$ on Lusk Creek (AK 02) in southern Illinois to 24,320 $Kg \cdot day^{-1}$ on the Vermilion River near Danville (BP 01). Baseline loads on the Wabash River at Hutsonville, Indiana (B 06) were 148,601 Kg $\cdot day^{-1}$. Baseline loads of inorganic nitrogen on the Embarras River did not follow the usual pattern of increasing in the downstream portions due to an increase in flow volumes. Baseline loads were higher in the upstream portions south of Charleston (BE 09) 18,657 $Kg \cdot day^{-1}$ versus 16,474 $Kg \cdot day^{-1}$ at BE 07 near Ste. Marie. This was due to a decrease in nitrate concentrations between the two stations.

Yields of inorganic nitrogen in the Ohio River basin were highest on Saline Branch

(BPJC06), 49.6 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$ and were greater than 25 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$ on the upper Embarras River (BE 14 and BE 09), Little Vermilion River (BO 07), Vermilion River (BP 01) and its tributaries North Fork Vermilion River (BPG 09) and Salt Fork Vermilion River (BPJ 07). Yields of inorganic nitrogen were less than 6.5 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$ in the Little Wabash River basin, Bonpas Creek, Lusk Creek, Cache River, South Fork Saline River and North Fork Embarras River (Figure 4-2).

Baseline loads of total nitrogen were available from seven stations in the Ohio River drainage. Nitrates were the predominant form of nitrogen loads on the Embarras River, Vermilion River and its tributaries North Fork Vermilion River and Middle Fork Vermilion River. Nitrogen in the form of ammonia and organic compounds was more prevalent on the Little Wabash, Lusk Creek and South Fork Saline River (Figure 4-3).

Figure 4-3. Comparison of total nitrogen loading composition on the Illinois River and its tributary stations. Illinois EPA AWQMN data October 1980 - September 1996.

Phosphorus

Since phosphorus can become bound to sediment particles (e.g., clay), baseline loads of total phosphorus can be affected by the suspended solids load in the river. Loads of dissolved phosphorus provide a distinct view of the differences between phosphorus that is dissolved into the water and that which is bound to sediments or organic matter. Streams in agricultural areas can have high total phosphorus loads but correspondingly low dissolved phosphorus loads reflecting that a significant portion of the phosphorus was attached to sediment particles. In contrast, streams which are dominated by point sources generally have high total phosphorus loads along with high dissolved phosphorus loads. For example, Bear Creek (KI 02) in western Illinois near Marcelline had a baseline load of total phosphorus of 1,193 $Kg \cdot day^{-1}$ and yield of 4.82 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$. The baseline load and yield of dissolved phosphorus was approximately one-tenth this amount: 110.7 $Kg \cdot day^{-1}$ and 0.45 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$ respectively, indicating that the total phosphorus load in Bear Creek was primarily attached to sediment particles. The Sangamon River near Niantic (E 05) is representative of phosphorus characteristics on a stream influenced by point sources. Baseline total phosphorus loads and yields were 1,991 $Kg \cdot day^{-1}$ and 2.66 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$ respectively. The baseline load and yield of dissolved phosphorus was approximately 80 percent of this amount: 1666.2 $Kg \cdot day^{-1}$ and 2.23 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$ respectively. The following discussion focuses on total phosphorus loads. Dissolved phosphorus loads were utilized primarily to help identify the sources of phosphorus (Tables 4-1).

Baseline loads of total phosphorus on the five Rock River stations ranged from 4,122 $Kg \cdot day^{-1}$ near Byron (P 14) to 7,031 $Kg \cdot day^{-1}$ near Joslin (P 04). The only other stations in Illinois (excluding the border streams) which exceeded these baseline loads of total phosphorus on the Rock River were the eight Illinois River stations. Yields of total phosphorus on the five Rock River stations ranged between 0.73 and 1.04 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$. As with inorganic nitrogen, baseline loads of total phosphorus were lower on the tributaries and ranged from 19 $Kg \cdot day^{-1}$ Coon Creek (PQF 07) to 971 $Kg \cdot day^{-1}$ on the Pecatonica River at Harrison (PW 01). Yields were somewhat higher on the Green River (1.16 to 1.83 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$) and Elkhorn Creek (1.81 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$) than the main stem or other tributaries (Tables 4-1, 4-2 and Figure 4-4).

On the Illinois River, baseline loadings of total phosphorus ranged from 24,902 $Kg \cdot day^{-1}$ near Hardin (D 01) to 10,845 $Kg \cdot day^{-1}$ at Marseilles (D 23). On the two tributaries which form the Illinois River, baseline loads of total phosphorus were 2,834 $Kg \cdot day^{-1}$ on the Kankakee River near Wilmington (F 01) and estimated to be (based on combining three stations) 6,600 $Kg \cdot day^{-1}$ from the Des Plaines River. Baseline loadings on the Chicago Sanitary and Ship Canal (GI 02) at 4,665 $Kg \cdot day^{-1}$, made up the bulk of the total phosphorus load on the Des Plaines River. Baseline loads of total phosphorus on the Iroquois River, a tributary to the Kankakee River, were 1,484 $Kg \cdot day^{-1}$ and comprised the majority of the total phosphorus loading into the Kankakee River. The Mazon River (DV 04), which is also upstream from the Illinois River at Marseilles, had a baseline loading of 183 $Kg \cdot day^{-1}$ (Figure 4-4).

Yields of total phosphorus on the Illinois River ranged from 1.16 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$ near

Hennipin (D 16), to 1.85 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$ near Marseilles (D 23). Yields of total phosphorus in the Des Plaines River basin were significantly higher, due primarily to point source discharges and to a lesser extent urban runoff, than in the Kankakee River basin. Where the Des Plaines River enters Illinois from Wisconsin (G 08), yields of total phosphorus were 0.49 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$. But near Riverside (G 39), the yield had increased to 2.55 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$. On the Chicago Sanitary and Ship Canal (GI 02) total phosphorus yields were 8.9 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$. Yields of total phosphorus on the Kankakee River near Wilmington (F 01) were 0.78 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$ (Figure 4-4).

Baseline loads of total phosphorus to the Illinois River from its major tributaries ranged from 1 $Kg \cdot day^{-1}$ on Slug Run (DJBZ01), a tributary to Big Creek in the Spoon River basin, to 3,845 $Kg \cdot day^{-1}$ on the Sangamon River near Oakford (E 25). The Spoon River and Fox River both contributed over 2,500 $Kg \cdot day^{-1}$ of total phosphorus to the Illinois River, followed by the Vermilion River and La Moine River at just over 1,650 $Kg \cdot day^{-1}$. Yields of total phosphorus were highest in the upper La Moine River (DG 04) 3.26 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$. However, yields of dissolved phosphorus at this station were only 0.34 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$ indicating that the total phosphorus load was primarily attached to sediment particles. Streams in the Illinois River basin where baseline phosphorus loads were significantly influenced by point source discharges, (based on high proportions of dissolved phosphorus loads) included Mauvaisse Terre Creek (2.82 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$); the Sangamon River near Decatur (see above) and Sugar Creek (EID 04) a tributary to Salt Creek in the Sangamon River basin (3.25 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$).

On the six Kaskaskia River stations, baseline loads of total phosphorus ranged from 178 $Kg \cdot day^{-1}$ downstream of the Lake Shelbyville dam (O 11) to 3,233 $Kg \cdot day^{-1}$ near Okawville (O 20). Baseline loads on tributaries to the Kaskaskia River ranged from 2 $Kg \cdot day^{-1}$ on Asa Creek (OZZT01) to 532 $Kg \cdot day^{-1}$ on Silver Creek (OD 07). Yields of total phosphorus in the Kaskaskia River basin were highest on streams receiving urban runoff or point source discharges and included Sugar Creek (OH 01) 4.11 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$, Richland Creek (OC 04) 3.77 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$, and Silver Creek (OD 06) 2.65 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$.

On the smaller direct tributaries to the Mississippi River, baseline loads of total phosphorus ranged from 3 $Kg \cdot day^{-1}$ on Pond Creek (NG 02) in the Big Muddy basin, to 1,587 $Kg \cdot day^{-1}$ on the Big Muddy River (N 12). On the Mississippi River, loads of total phosphorus increased from 24,766 $Kg \cdot day^{-1}$ at Fulton (M 04) to 47,844 $Kg \cdot day^{-1}$ at Keokuk (K 04). Yields of total phosphorus also increased from 0.41 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$ at Fulton (M 04) to 0.57 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$ at Keokuk (K 04) (Tables 4-1 and 4-2).

In the Ohio River basin, baseline loads of total phosphorus ranged from 3 $Kg \cdot day^{-1}$ on Lusk Creek to 2,854 $Kg \cdot day^{-1}$ on the Little Wabash River (C 23). Baseline loads of total phosphorus on the Wabash River at Hutsonville, Illinois were 3,016 $Kg \cdot day^{-1}$. As with other watersheds, yields of total phosphorus were highest on streams which received urban runoff or wastewater treatment plant discharges. Yields ranged from 0.11 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$ on Lusk Creek to 4.37 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$ on Saline Branch . Yields of dissolved phosphorus were less than 0.7 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$ with the exception of Saline Branch (BPJC06) which was 4.0 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$(Figure 4-4).

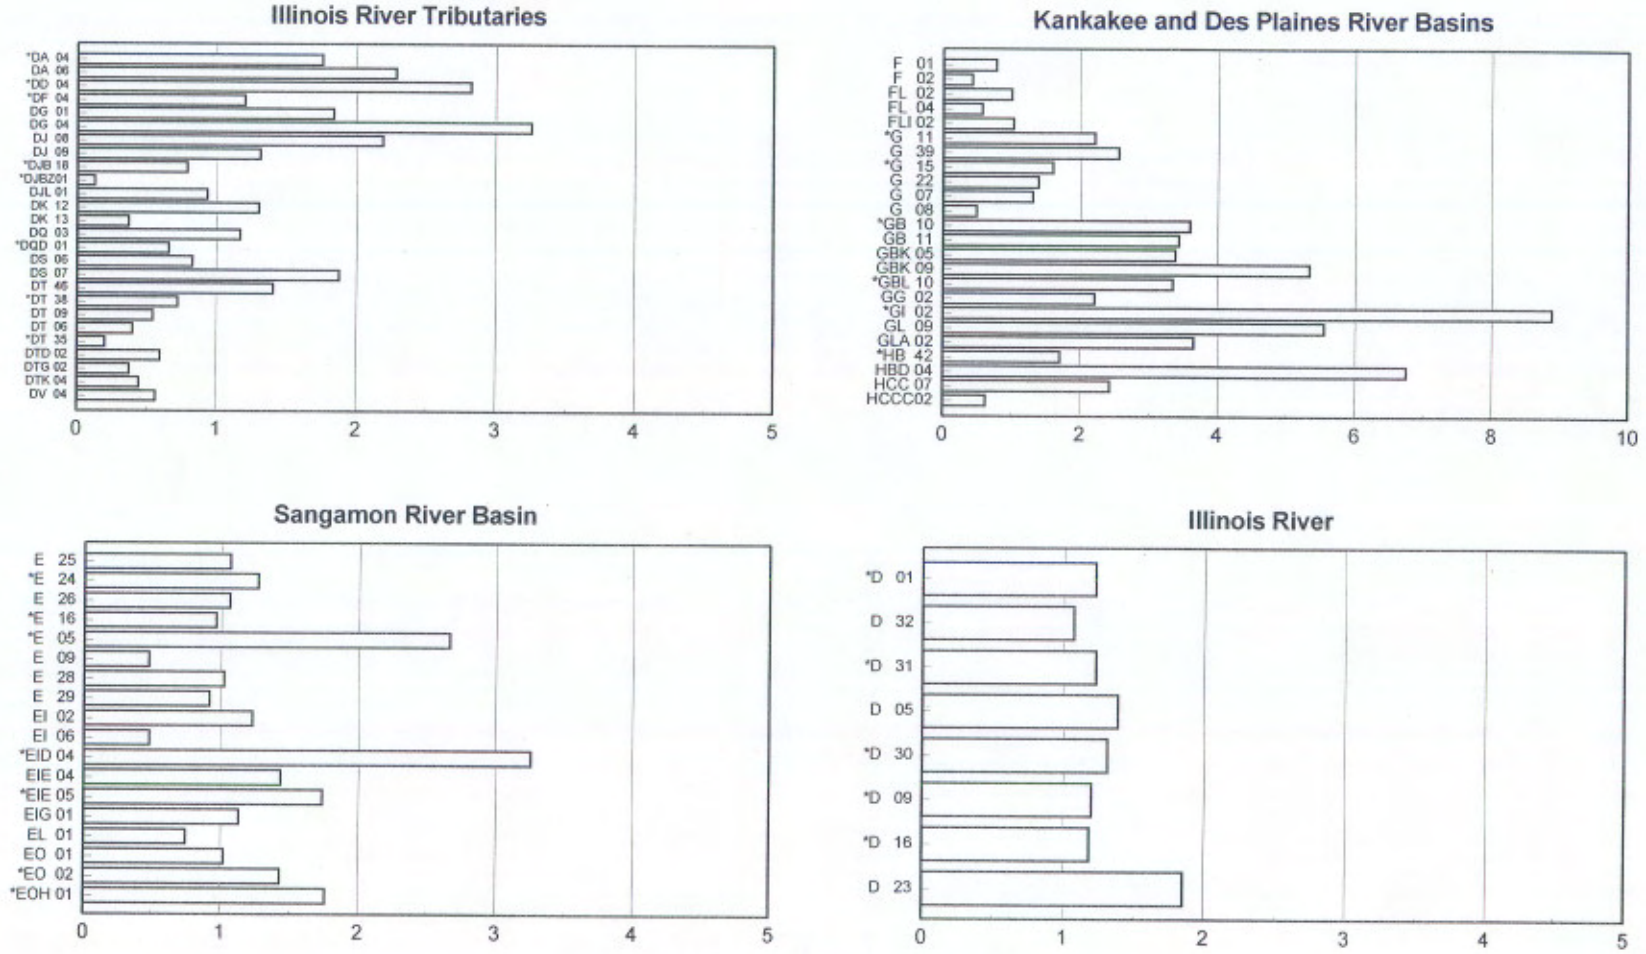
Figure 4-4 (cont) . Comparisons of baseline yields of total phosphorus (Kg/Hectare/Year). Illinois EPA AWQMN data October 1980 - September 1996.



Total Suspended Solids

Baseline loads of total suspended solids on the Rock River ranged from 860,933 $Kg \cdot day^{-1}$ near Byron (P 14), to 2,372,328 $Kg \cdot day^{-1}$ near Joslin (P 04). Unlike nitrogen and phosphorus, the maximum baseline suspended solids loadings on the Rock River were exceeded on two streams in addition to the Illinois River main stem: the Spoon River (DJ 08) and Mackinaw River (DK 12). Yields of total suspended solids on the five Rock River stations ranged from 152 to 350 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$. Yields on two tributaries to the Rock River were significantly higher: the Green River, PB 04 (702 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$) and Elkhorn Creek, PH 16 (1,535 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$) (Figure 4-5).

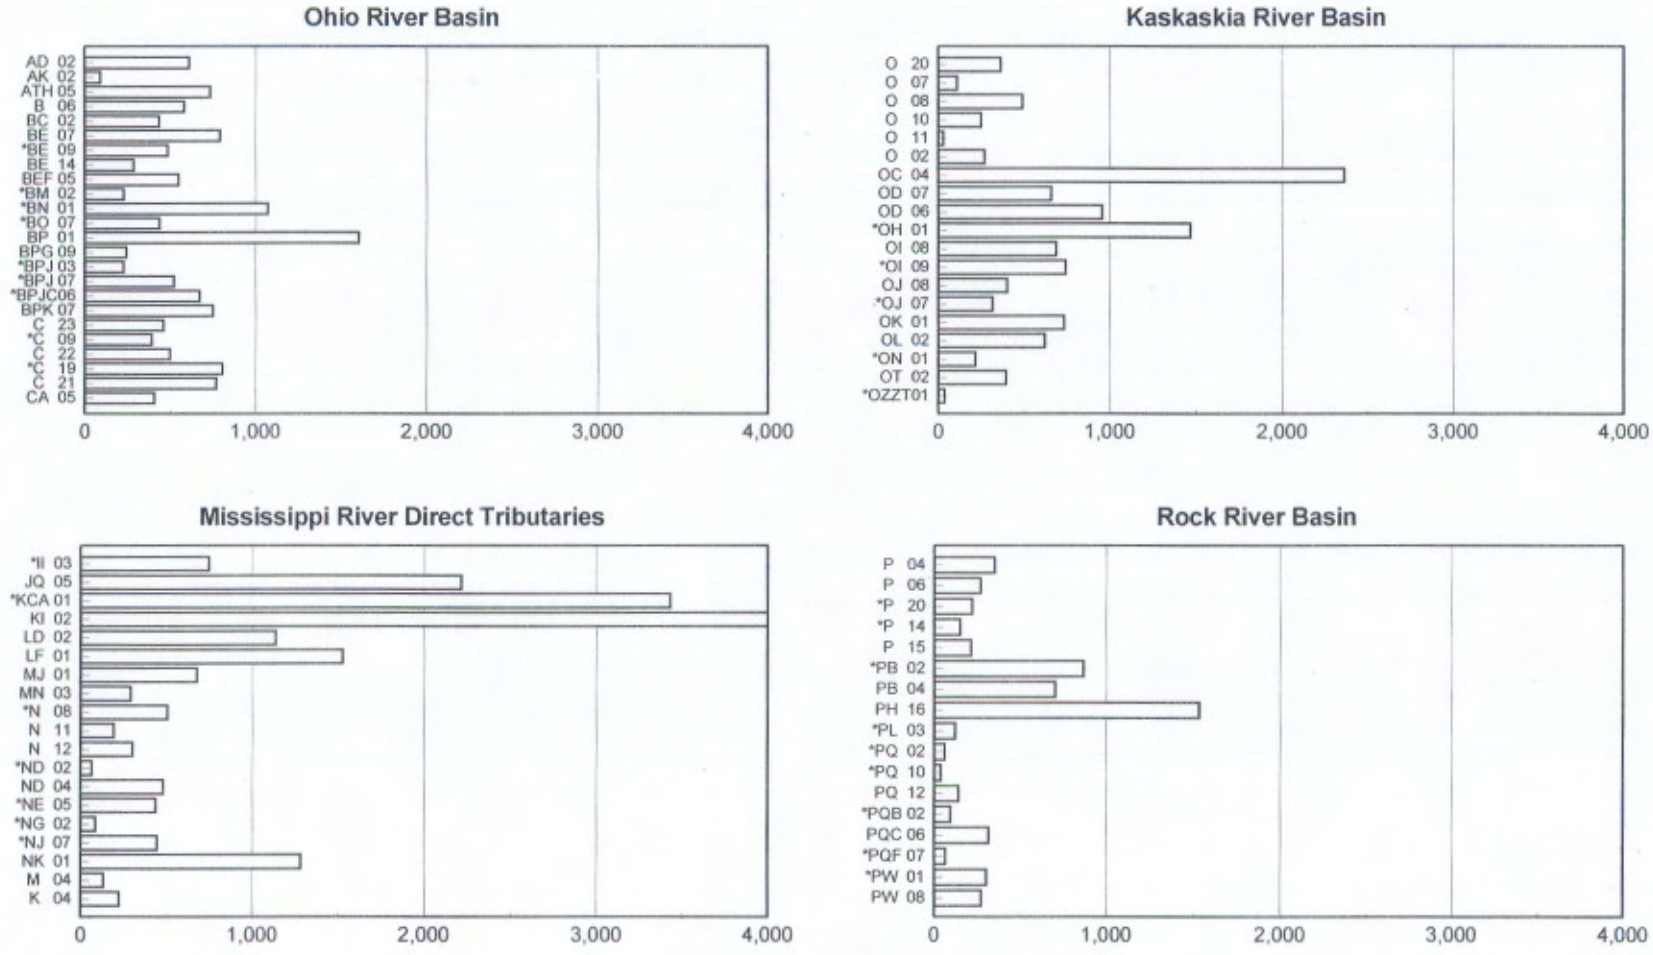
On the Illinois River, baseline loads of total suspended solids ranged from 1,811,678 $Kg \cdot day^{-1}$ near Marseilles (D 23), to13,875,624 $Kg \cdot day^{-1}$ near Hardin (D 01). The Kankakee River near Wilmington (F 01) had a baseline loading of 1,468,303 $Kg \cdot day^{-1}$. The Iroquois River (FL 02) was a major contributor to the loads in the Kankakee River with a baseline loading of 772,481 $Kg \cdot day^{-1}$. The Des Plaines River (based on combining three stations: G 11, GB 11 and GI 02) was estimated to have a baseline load of 304,836 $Kg \cdot day^{-1}$. On major tributaries to the Illinois River, the largest contributors of baseline loadings of suspended sediments were the Spoon River at DJ 08 (2,663,539 $Kg \cdot day^{-1}$) and the Mackinaw River at DK 12 (2,717,971 $Kg \cdot day^{-1}$). The Sangamon River (E 25) was also a large contributor of baseline loadings with 2,035,757 $Kg \cdot day^{-1}$. Two other tributaries to the Illinois River, the Fox River and Vermilion River, contributed more than 1,000,000 $Kg \cdot day^{-1}$ of total suspended solids.

Yields of total suspended solids in the Illinois River basin were generally lower on stations in the Fox River watershed when compared with the other watersheds. Yields were less than 180 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$ with the exception of the farthest downstream station on the Fox River. Yields of total suspended solids were greater than 1,500 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$ on Macoupin Creek, Indian Creek (DF 04), La Moine River, Spoon River and its tributary Indian Creek (DJL 01), Mackinaw River, two tributaries to the Sangamon River (Sugar Creek and Kickapoo Creek) and West Bureau Creek (Figure 4-5).

On the six Kaskaskia River stations, baseline loads of total suspended solids ranged from 20,571 $Kg \cdot day^{-1}$ below Lake Shelbyville (O 11), to 1,134,907 $Kg \cdot day^{-1}$ at the farthest downstream station near Okawville (O 20). Baseline loadings exceeded 200,000 $Kg \cdot day^{-1}$ from stations on Richland Creek (OC 04), Silver Creek (OD 07) and Shoal Creek(OI 08). Yields of total suspended solids were highest on Richland Creek (OC 04) 2,365 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$ and Sugar Creek near Albers (OH 01) 1,468 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$(Figure 4-5).

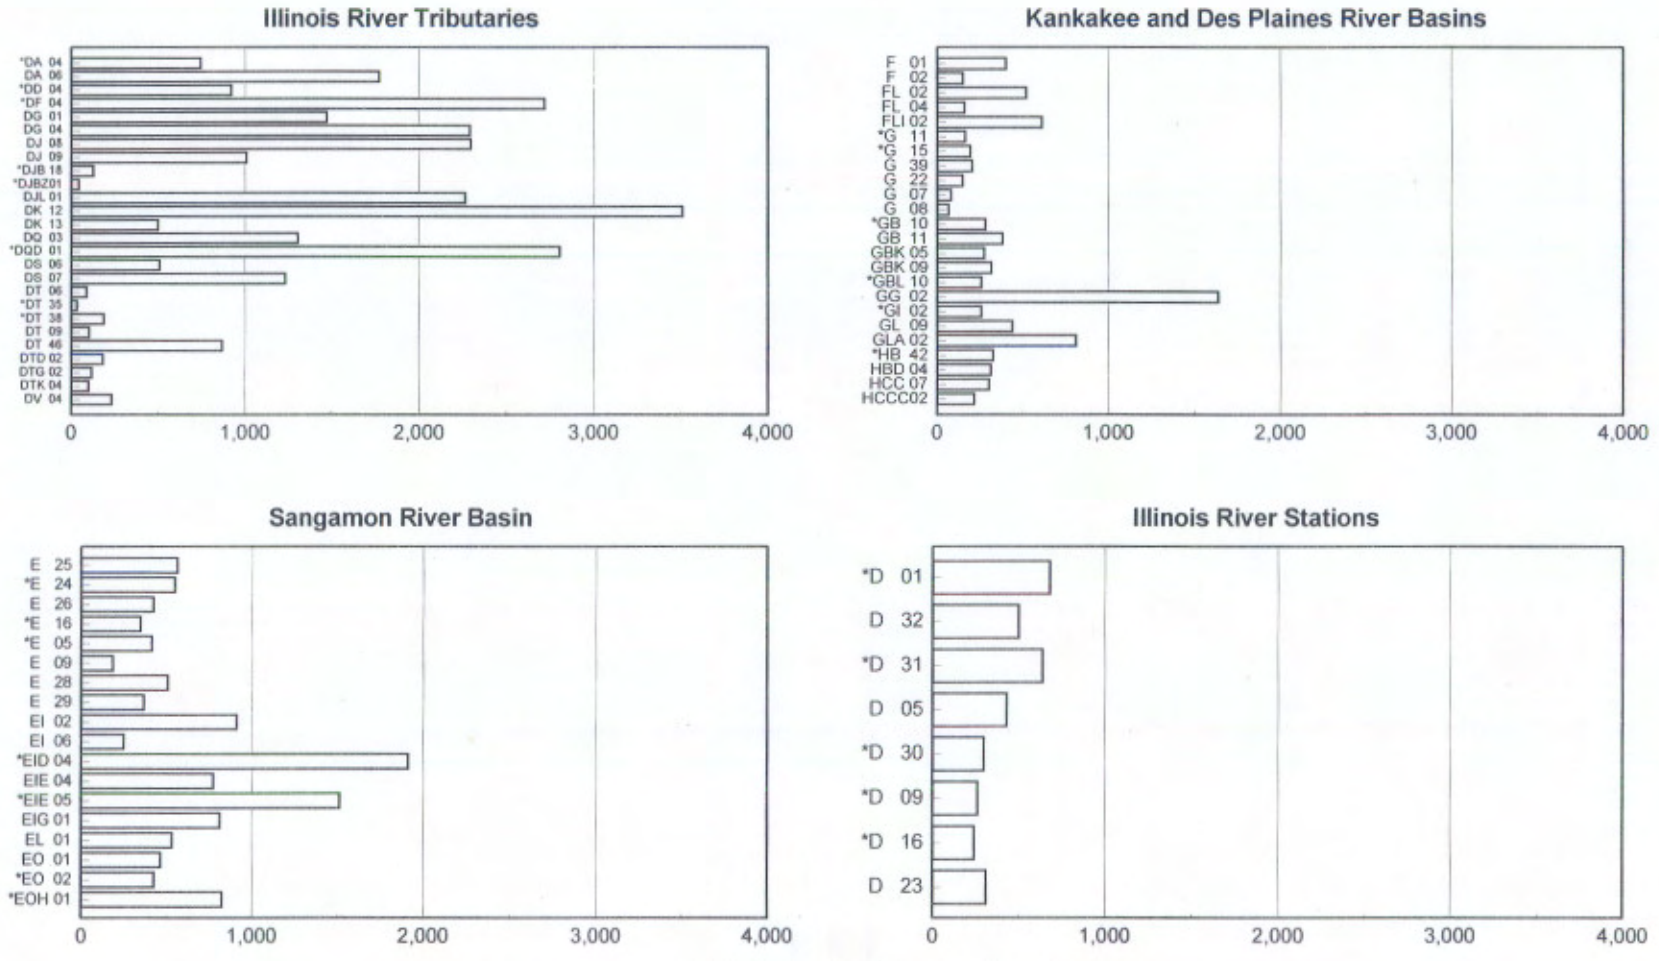
On the smaller direct tributaries to the Mississippi River, baseline loadings of total suspended solids ranged from 59,945 $Kg \cdot day^{-1}$ on Marys River (II 03) to 1,692,382 $Kg \cdot day^{-1}$ on Bear Creek near Marcelline (KI 02). Yields from Bear Creek were the highest of any of the stations reviewed, 6,839 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$. The values on Bear Creek were affected by a sample collected during the highest flow event recorded on Bear Creek. On the Mississippi River, loads

Figure 4-5. Comparisons of baseline yields of TSS (Kg/Hectare/Year). Illinois EPA AWQMN data October 1980 - September 1996.



* indicates less than 16 years of flow data

Figure 4-5 (cont). Comparisons of baseline yields of TSS (Kg/Hectare/Year). Illinois EPA AWQMN data October 1980 - September 1996.



* indicates less than 16 years of flow data

of total suspended solids increased from 8,096,760 $Kg \cdot day^{-1}$ at Fulton (M 04) to 19,019,448 $Kg \cdot day^{-1}$ at Keokuk (K 04). Yields of total phosphorus also increased from 133 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$ at Fulton (M 04) to 225 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$ at Keokuk (K 04) Tables 4-1 and 4-2.

In the Ohio River basin, baseline loads of total suspended solids ranged from 2,786 $Kg \cdot day^{-1}$ on Lusk Creek (AK 02) to 1,469,210 $Kg \cdot day^{-1}$ on the Vermilion River at Danville (BP 01). The extremes of yields also occurred at these two stations and ranged from 91 to 1,606 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$ respectively. Baseline loads of TSS on the Wabash River at Hutsonville, Illinois, were 5,375160 $Kg \cdot day^{-1}$. Baseline loads on the Little Wabash River and Embarras River exceeded 850,000 $Kg \cdot day^{-1}$. TSS yields were highest on the Vermilion River and Brouillets Creek where they exceeded 1000 $Kg \cdot Ha^{-1} \cdot Yr^{-1}$ (Table 4-2).

Discussion

Baseline loadings to the Mississippi River from Illinois streams generally followed the pattern of flow (Figure 4-6). Streams with the highest mean flows had the highest baseline loads (Figure 4-7). The Illinois River had the highest baseline loadings of inorganic nitrogen, phosphorus and suspended sediment, followed by the Rock River. The Kaskaskia River was the third largest source of baseline loadings of inorganic nitrogen and total phosphorus to the Mississippi River from Illinois. However, baseline loads of both inorganic nitrogen and total phosphorus from the Kaskaskia River were exceeded by the combined baseline loads of the smaller direct tributaries. Baseline loads of inorganic nitrogen on the Kaskaskia River were significantly effected by the two large reservoirs. Bear Creek had the third highest baseline loading of total suspended solids due primarily to a sample collected during a record flow event.

In the upper portions of the Illinois River, the Des Plaines River drainage was the major source of baseline loadings of total phosphorus (Figure 4-8). The high dissolved phosphorus loadings indicated that the majority of the phosphorus leaving the Des Plaines River was coming from point sources. In contrast, baseline loadings of inorganic nitrogen to the upper portion of the Illinois River were slightly higher on the Kankakee River than the Des Plaines River. The Kankakee River was also the primary source of baseline total suspended solids loadings in the upper Illinois River. Both the Kankakee River and Des Plaines River were influenced by their two tributaries, the Iroquois River and the Chicago Sanitary and Ship Canal respectively. Further downstream on the Illinois River, the Sangamon River basin was the largest contributor of baseline loads of inorganic nitrogen and phosphorus to the Illinois River (Figure 4-8). Baseline loads of total suspended solids to the Illinois River were highest in the Spoon River and Mackinaw River basins (Figure 4-9)

In the Ohio River basin, baseline loadings did not follow the flow pattern (Figure 4-6). Although the Little Wabash River has roughly double the daily mean flow of either the Vermilion River or Embarras River, it contributed less than half as much baseline loadings of inorganic nitrogen due to significantly lower concentrations of nitrates (Table 4-10). The

Vermilion River had the highest baseline loadings of inorganic nitrogen followed by the Embarras River. The Little Vermilion River, with a drainage area of 495 Km^2 (191 $miles^2$) and Brouillets Creek, with a drainage area of 670 Km^2 (260 $miles^2$), had a combined inorganic nitrogen load that was slightly higher than the entire Little Wabash River watershed, 7,998 Km^2 (3,088 $miles^2$), due to much higher concentrations of nitrates in these streams. Conversely, the Little Wabash River had the highest baseline loads of total phosphorus followed by the Embarras River and then the Vermilion River. Baseline loads of total suspended solids were also highest on the Vermilion River. TSS loads were similar on the Embarras River and Little Wabash River (Figure 4-10).

Determining the effects of point source versus nonpoint sources, which includes agriculture, aerial deposition and natural effects, on loads is difficult for a variety of reasons. Point source discharges in Iliinois are required by their NPDES permits to routinely monitor flow and total ammonia-N in their effluents, but not other forms of nitrogen (nitrates and TKN) or phosphorus. Sewage treatment lagoons, which may have little, if any, discharge during the summer months, are not required to report even ammonia. This makes estimations of point source loads versus nonpoint or background loads impractical. Tetra Tech (1998) attempted to determine point source loads in the Mississippi River basin based on subsampling of six different effluent flow categories. They concluded that a flow-weighted load average was not a defensible method due to the lack of data. They relied on a census approach rather than a statistical approach to estimate loads from point sources. Other studies have used models in an attempt to determine the percentages of loads due to point sources versus nonpoint sources (Lovejoy, 1992). Although the Illinois EPA collects a wide range of parameters from effluents through several programs (Table 4-3), the author was unable to accurately delineate portions of loads attributed to point sources within specific watersheds.

Table 4-3. Summary of effluent nutrient concentrations collected during facility related stream surveys by the Illinois EPA between 1987 and 1996.

	Water Temperature C	Total Ammonia-N	Total $NO_3 + NO_2$-N	TKN	Total Phosphorus

5. EXPORT OF NUTRIENTS FROM ILLINOIS -- 1996 Water Year

Introduction

In January 1998, water quality specialists from the Illinois EPA, Illinois State Water Survey, IDNR Office of Water Resources, and Department of Agriculture convened a workgroup know as the Illinois Nutrient and Sediment Assessment workgroup or INAS. One of the goals of the group was to evaluate loadings by year for comparison with a national nutrient loadings assessment being conducted by the USGS and NOAA. The national assessment was being driven by "hypoxia" or anoxic conditions in the Gulf of Mexico (Rablais et al., 1998). The national assessment was based in part on the assumption that nutrients from the Mississippi River watershed were significant contributors to the water quality problems in the Gulf of Mexico (Winstanley, 1999).

Twenty-one Illinois EPA AWQMN stations, which were located at the farthest downstream USGS gage station within their respective watersheds, were selected to develop these nutrient loading estimates (Figure 5-1, Table 5-1). The drainage area from the 21 stations covered 48,195 miles^2 of the surface area of Illinois (86.4 percent). The period of record was the same as the baseline loading project, October 1980 through September 1996. Daily mean flow data for the period October 1980 through September 1996, was available from the USGS (via the Internet) at all the stations except for the Plum River. Estimates of flow on Plum River from October 1980 to September 1994 were based on a relationship with Apple River. Regression analysis of daily flow data from the Plum River collected from October 1994 through September 1996 (n = 731 samples) with the Apple River during this same time frame, resulted in the following equation:

1.036 * Apple River flow = Plum River flow. The R squared value was 0.755.

Loadings at four additional stations located along streams bordering Illinois were also calculated for comparisons. These stations included two sites on the Mississippi River: Keokuk, Iowa (K 04) and Thebes, Illinois (I 84); the Ohio River near Olmstead, Illinois (A 06) and the Wabash River near Hutsonville, Illinois (B 06).

Data Analysis Methods

Although the baseline loadings previously presented provide a reasonable estimator of flux from the state of Illinois, and how loadings are distributed statewide, a method was needed to separate loads into individual years. Since ambient water quality samples collected by the Illinois EPA were based on a fixed sampling cycle independent of flow events they could be characterized as fixed load. For constituents whose concentrations were significantly correlated with flow, a fixed sampling network would tend to underestimate the actual loads particularly if

*Wabash River flows based on USGS gage at Riverton, Indiana.
**Ohio River flows based on USGS gage at Metropolis, Illinois.

high flow events were missed. By utilizing the relationship between daily flow values from USGS gage stations and concentration of a parameter, it was reasoned that a more accurate estimate of loads in a given year or season could be calculated.

Correlation analysis, which measures the closeness of a relationship between two variables (Snedecor and Cochran, 1980), was performed at each station between concentrations of total ammonia-N, total Kjedahl nitrogen, total nitrate + nitrite nitrogen, total phosphorus, dissolved phosphorus, total suspended solids and flow. Because of the known influence of seasonality, particularly on nitrate concentrations, correlations between the parameters and water temperature were also conducted. A PROC CORR statement in SAS was utilized to calculate a Pearson correlation coefficient (SAS 1985). The null hypothesis (H_o)was that there was no significant correlation at the $P < 0.05$ level.

The first method reviewed to calculate annual loads was based on flow weighted averages where the mean concentration was multiplied by the mean flow over the averaging period. This method works well when there is a poor relationship between concentration and flow. The main weakness of this method is that it fails to address seasonal variability which can be an important factor particularly with nitrates. A computer program developed by Walker (1996) was used to calculate flow weighted loadings. Comparisons were also made between daily flows during the 16 year period of record and flows on days when water quality samples were collected at the 21 interior stations. The data was stratified into three layers to increase precision:

less than 0.5 * Qmean;
between > 0.5 * Qmean and < 2 * Qmean; and,
greater than 2 * Qmean;

where Qmean was the mean flow during the 16 year period of record.

The second method used to calculate annual loads was based on a regression equation developed by Cohn et al. (1992) (see also Langland, 1995). This method estimates concentrations at various flow rates and time of the year. The regression equation has seven estimated parameters: a constant; a quadratic fit to the logarithm of discharge (β_1 and β_2); a quadratic fit to time (β_3 and β_4); and a sinusoidal (first-order Fourier) function to remove the effects of seasonality (β_5 and β_6). It can be written as:

$$\log [C] = \beta_0 + \beta_1 \log(Q/Q') + \beta_2 [\log(Q/Q')]^2 + \beta_3 [T - T'] + \beta_4 [T - T']^2 + \beta_5 \mathrm{Sin}(2\pi T) + \beta_6 \mathrm{Cos}(2\pi T) + \epsilon$$

Where C is the concentration in mg/L, Q is the discharge in cubic feet per second, T is time measured in decimal years, Q' and T' are centering variables for discharge and time respectively. Errors, denoted by ϵ, were assumed to be independent and normally distributed with zero mean and variance. A variation of the Cohn method where log [C] was replaced with log [Q_L] (flow) was also reviewed (Robertson, 1997). The regression model, using concentrations, was selected

as the primary method to estimate loads from Illinois since it was believed that it could be directly compared to the national assessment. Loads were calculated using the formula: $L_d = Q_d * C_{it} * K$; where L_d was the load in tons per day; Q_d was the daily mean discharge in cubic feet per second; C_{it} was the estimated constituent concentration based on the discharge and time of year in mg/L; and K = 0.0027 is the conversion factor to tons per day. Daily loads based on the regression equation were then added together to provide annual and period of record loads. Loads were converted from tons to kilograms for the purpose of this report.

Because of errors due to the re-transformation of logarithmic estimates of concentrations and loads in these models, two methods were evaluated to estimate correcting factors that could be applied to remove the bias (Gilroy et al., 1990). The Quasi-Maximum Likelihood Estimator (QLME) assumes a normal distribution of the log transformed data. The Duan Smearing Estimator (DSE), uses a non-parametric procedure to correct for the bias in the median estimate. The QLME and DSE give similar results if the distribution of the residuals are fairly normal, the number of samples is larger than 30 and the variance is small. When these conditions are not met, the DSE provides estimates that are closer to the true values. The Duan Smearing Estimator was selected as the method for this data set.

In order to evaluate the accuracy of the regression models, load data from the 1997 water year was compared with loads predicted by the regression equation using the same mean daily flows. A paired *t-test* was used and the null hypothesis (H_o) was that there were no significant differences between the actual means and the predicted means at the $P < 0.05$ level. Only 17 of the stations had flow data available at the time of the comparison. Sample sizes were small and included nine samples from all sites except the Rock River and Green River where only eight samples were available. In addition, the values were graphed to visually inspect any differences. Comparisons between annual mean loads based on the regression equation and those calculated from the baseline loading portion of the report and the flow weighted method were also conducted. The relative percent difference (RPD) was calculated as the sum of two times the mean annual load based on the regression equation minus the load from the other method divided by the mean annual load based on the regression equation plus the load from the other method divided by the number of samples: $\sum(2*(a-b)/(a+b))/n$.

In order to calculate the amount of inorganic nitrogen (nitrates plus ammonia) and phosphorus leaving Illinois on average over the period studied or specifically the 1996 water year, several adjustments to the data were necessary. Since stations were not located at the mouth of the rivers, the load was increased by the ratio of drainage area at the monitoring station to the drainage area at the mouth (Table 5-1). On basins which had multiple stations, the loads and areas were combined before calculating the overall flux from that watershed. These included adding the Green River with the Rock River; Macoupin Creek with the Illinois River at Valley City; Silver Creek and Richland Creek to the Kaskaskia River; and the North Fork Embarras River with the Embarras River. Loads of total nitrogen (TKN plus nitrates) were calculated at stations where the data was available.

Results and Discussion

Correlation coefficients for the 21 stations are presented in Table 5-2. Total suspended solids concentrations were significantly correlated with flow at 16 of the 21 stations. Flows on three of the five streams where there was a lack of significant correlation between total suspended solids concentrations and flow, the Illinois River, Kaskaskia River and the Big Muddy River, were affected by either navigation dams or large reservoirs. Total phosphorus concentrations were significantly correlated with flow at 13 of the 21 stations. This correlation was negative (both total and dissolved phosphorus concentrations increased with a decrease in flow) on the Illinois River probably due to the effects of point sources on phosphorus concentrations. Dissolved phosphorus also had significant negative correlations with flow on streams where point sources could affect concentrations during low flows and included the Vermilion River, Henderson Creek, Illinois River and Richland Creek. Dissolved phosphorus concentrations were positively correlated with flow at 10 additional stations (Table 5-2).

The number of statistically significant correlations between the concentrations of the three measures of nitrogen and flow were lower than those for either phosphorus or total suspended solids. Only six of the 21 stations had a significant positive correlation between nitrate concentrations and stream flow. On the Kaskaskia River basin tributary stations, Silver Creek and Richland Creek, nitrates had a significant negative correlation with stream flow. The negative correlation between nitrates and flow were probably due to the influence of point source discharges on nitrogen concentrations in those streams. Nitrate concentrations were also checked against water temperature since nitrates show strong seasonal variations in concentration. Significant negative correlations occurred between nitrates and water temperature at 14 of the 21 interior stations (i.e., as temperature goes up, concentrations of nitrates decrease). This indicates that seasonality may be more of a factor in nitrate concentrations than flow. The Green River was the only stream where concentrations from all six parameters were significantly correlated with flow (Table 5-2).

Since the chemical data was collected independent of flow events (i.e., high flows, spills) comparisons of sampling frequency with flow data was an important consideration. High flow events can account for the majority of loading in a given year, particularly on small streams or streams with rapid and easily altered flow profiles. Comparisons with flow data indicated that AWQMN sampling occurred at approximately the same frequency as flow events. With the exception of the stations on the Illinois River, Rock River and Green River, flows in the higher tier (ie. > 2 * Qmean) accounted for 15 percent or less of the samples collected and flow events, but represented 50 to 70 percent of the flow volume (Figure 5-2 and Table 5-3). Mean flows during the 16 year study period were higher than long term daily mean flows. This was reflected in the fact that maximum historical flows occurred at eight of the 21 stations over the 16 year study period (Table 5-1). Water quality samples corresponding with these record flow events occurred on Bear Creek, Vermilion River and Big Muddy River. Rainfall was also above long term averages in Illinois during much of the 16 year period (Figure 5-3).

Table 5-2. Summary of Pearson correlation coefficients of concentrations versus flow (cfs) or water temperature for data collected between October 1980 and September 1996 from the Illinois EPA AWQMN.

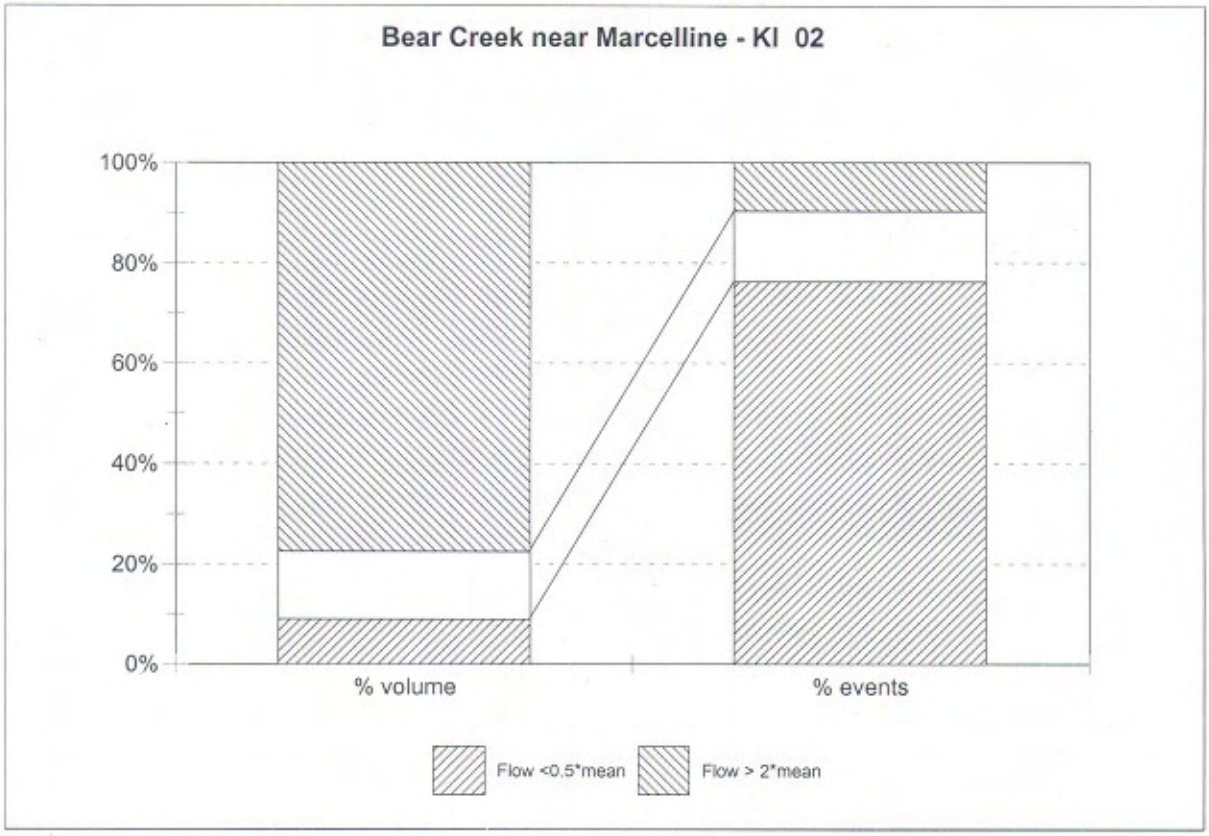
Breakdowns of flow are based on less than half the mean, and greater than 2 times the mean.

Figure 5-2. Comparison of Illinois EPA sampling frequency with flow frequency.



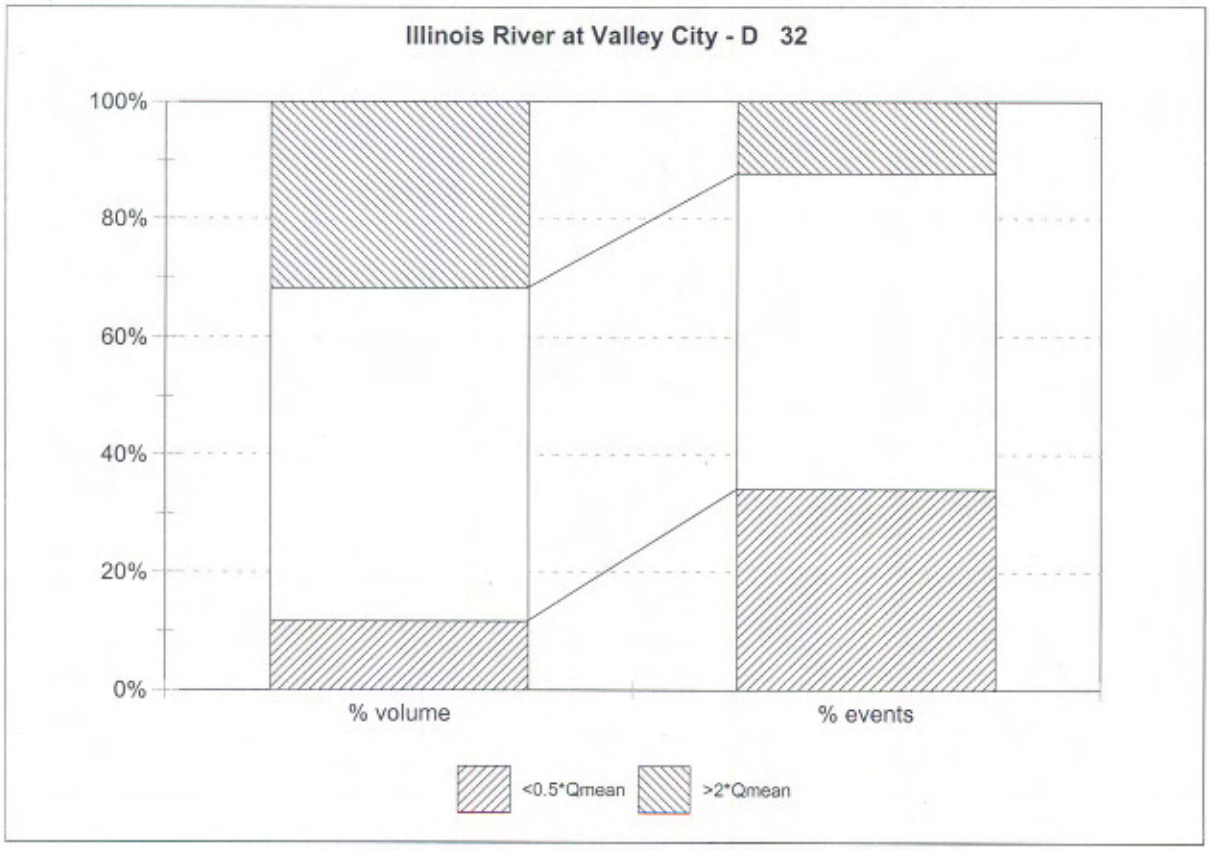


Figure 5-3. Illinois statewide rainfall data.

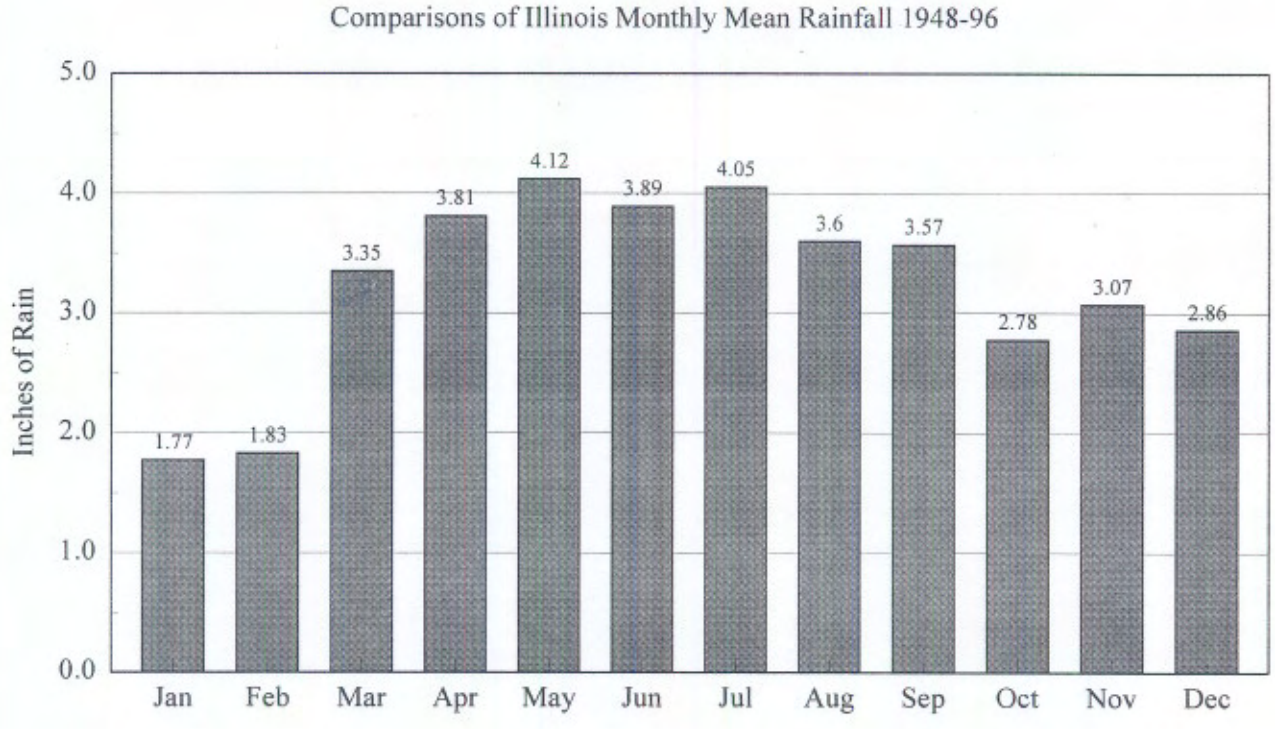
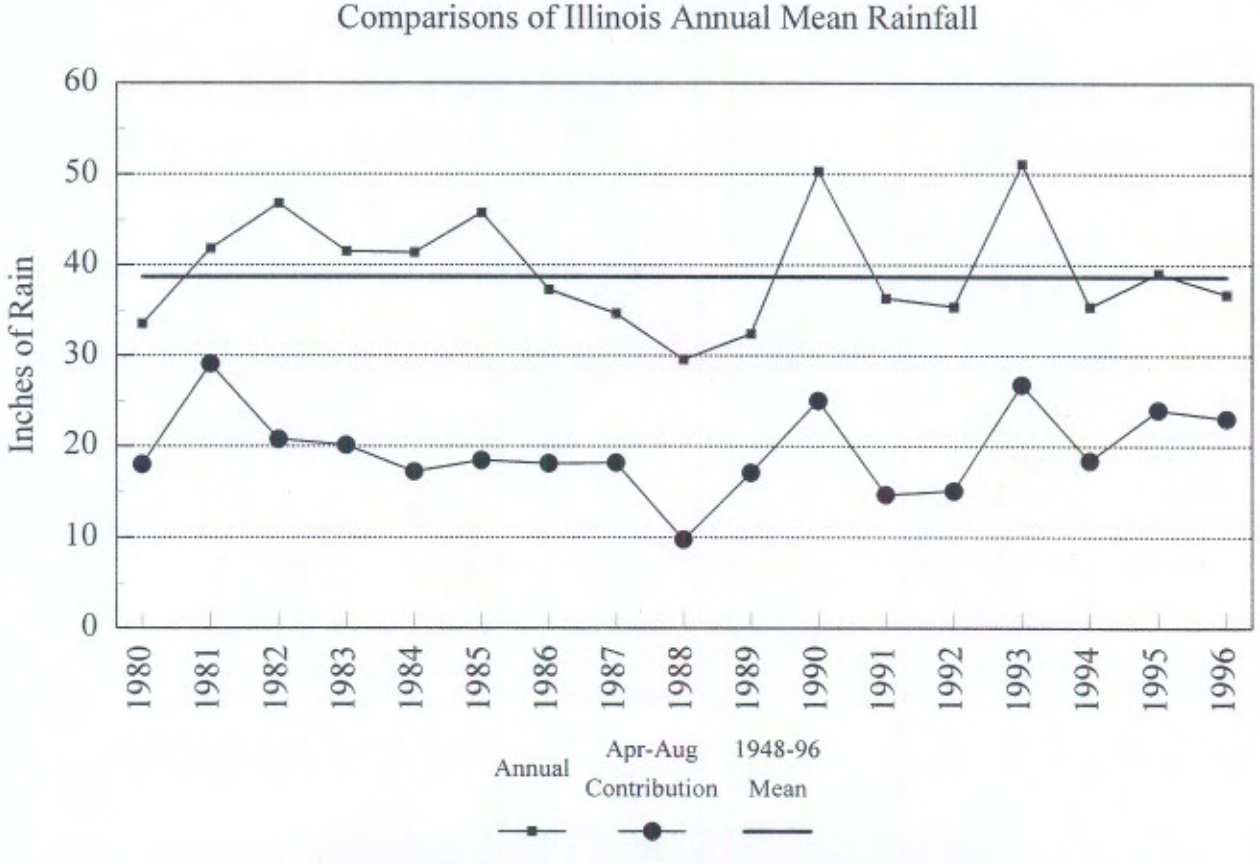




Although the chemical data set was scanned for outliers which were removed as appropriate, the same consideration had not been given to flow values. The rationale was that including extreme flow events, which can account for a significant portion of the loads, would improve the results of the regression analysis. However, after the initial calculations of loads using the Cohn [C] method, it appeared that two stations, Bear Creek (KI 02) and the Vermilion River (BP 01), had fluxes which were disproportionate to their drainage area. For example, the flux of suspended sediment from Bear Creek was greater than that from the Illinois River at Valley City. A closer inspection of the effects of these extreme flow events on the regression equations was necessary.

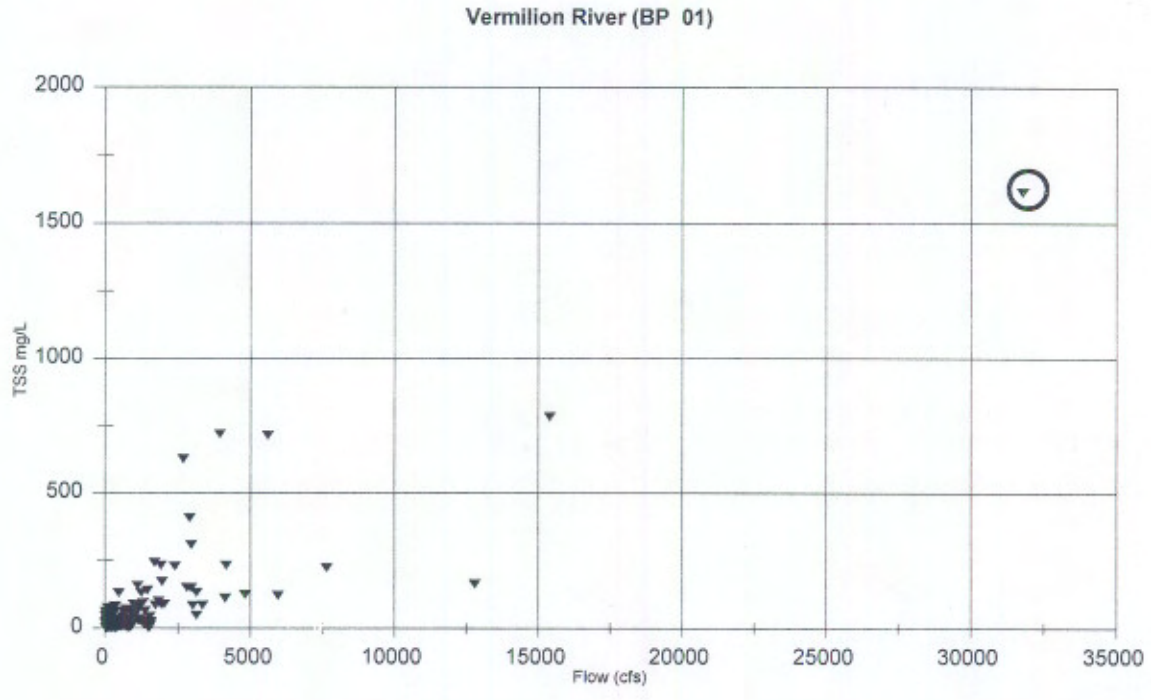
On Bear Creek, the maximum daily flow occurred on March 4, 1985, and corresponded with the collection of a water quality sample by the Illinois EPA . The instantaneous flow was 24,600 cfs and the daily mean flow value was 20,500 (Figure 5-4). This was the highest daily mean flow ever recorded for Bear Creek and contained the highest concentration of total phosphorus, 1.7 mg/L in the data set. During this high flow event, total suspended solids concentrations were 2500 mg/L; however, lower flows had resulted in higher concentrations of suspended solids in Bear Creek (i.e., 4,620 mg/L TSS occurred at 3,480 cfs). For the 16 year period of record on Bear Creek, the 95th percentile of flow was 1,500 cfs and the 99th percentile was 5,270 cfs. Removal of the high flow record from the regression equation resulted in loads of inorganic nitrogen showing an 11.7 percent decrease. Loads of both phosphorus (82.3 percent) and TSS (93.8 percent) showed more significant decreases.

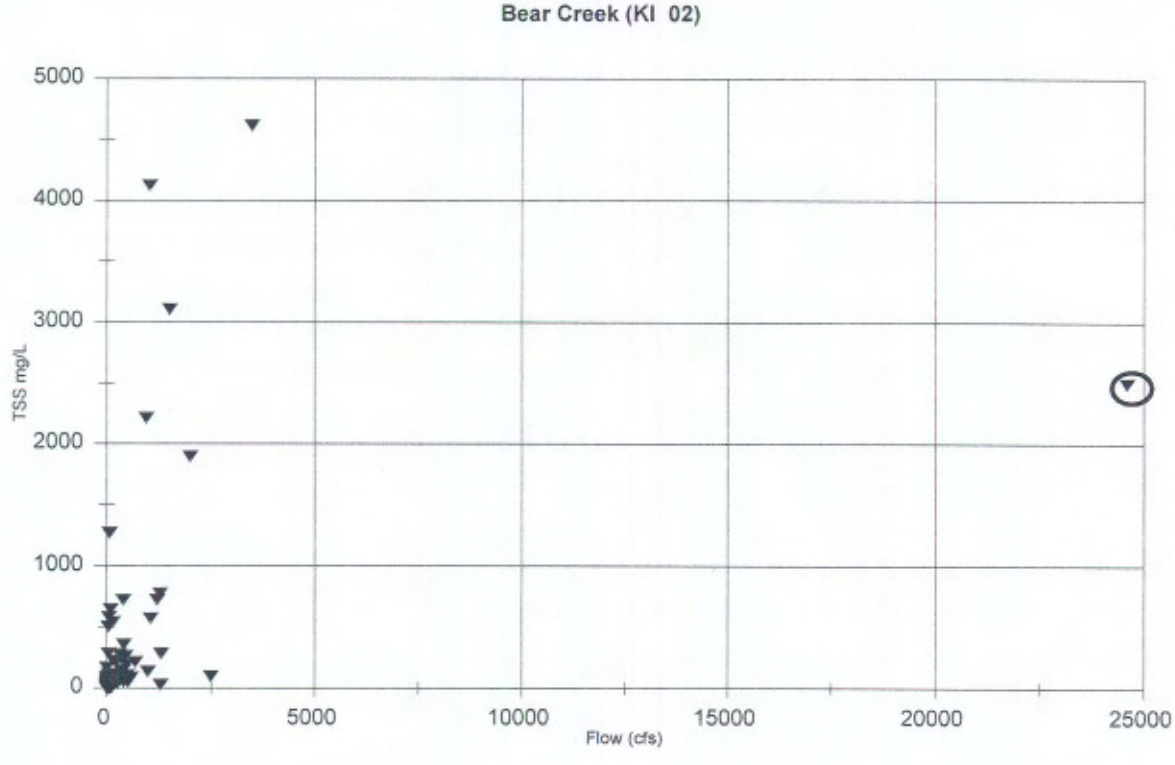
Bear Creek (KI 02)	Inorganic- N	T Phosphorus	TSS
Cohn-C with max flow	958,910 Kg·year^{-1}	942,581 Kg·year^{-1}	5,512,753,210 Kg·year^{-1}
Cohn-C w/o max flow	845,329 Kg·year^{-1}	166,108 Kg·year^{-1}	341,047,688 Kg·year^{-1}

On the Vermilion River near Danville record flows occurred during April, 1994, with the maximum value 45,100 cfs on April 13. The Illinois EPA collected a sample from this station on April 12, 1994, when the daily mean flow was 31,800 cfs (2nd highest on record) Figure 5-4. Total suspended solids concentrations were 1,615 mg/L on that date, more than double the previous high of 716 mg/L which occurred at a flow of 5,620 cfs. For the 16 year period of record, the 95th percentile of flow on the Vermilion River at Danville was 5,070 cfs and the 99th percentile was 11,200 cfs. Removal of the high flow record from the regression equation, resulted in loads of nitrogen showing an 8.7 percent increase and loads of phosphorus showing a 16.8 percent decrease. Loads of total suspended solids showed the most dramatic decrease, 70.9 percent.

Vermilion River (BP 01)	Inorganic-N	T Phosphorus	TSS
Cohn-C with max flow	9,141,854 Kg·year^{-1}	450,878 Kg·year^{-1}	2,103,955,560 Kg·year^{-1}
Cohn-C w/o max flow	9,937,650 Kg·year^{-1}	409,873 Kg·year^{-1}	612,636,877 Kg·year^{-1}

Figure 5-4. Flow outliers from Bear Creek(KI) and the Vermilion River (BP).





The wastewater treatment plant at Danville has a significant effect on phosphorus and nitrogen concentrations at this site particularly during low flow conditions.

Other stations where maximum flow events occurred during ambient water quality sampling were also examined to evaluate the effect of these events on predicted loads. On the Big Muddy River the maximum flow, 33,500 cfs, occurred on May 2, 1996. The Illinois EPA sampled the site on May 1, 1996, when the flow was 29,200 cfs. Total suspended solids concentrations in this sample were 176 mg/L. Higher concentrations of total suspended solids had occurred on the Big Muddy River at lower flows (243 mg/L at 2,850 cfs and 314 mg/L TSS at 3,230 cfs). For the 16 year period of record the 95th percentile of flows was 9,160 cfs and the 99th percentile was 17,300 cfs. Removal of the high flow record from the regression equation resulted in only minor changes in the calculated loads on the Big Muddy River. Inorganic-N loads increased 1.2 percent; phosphorus loads decreased 3.7 percent and TSS loads decreased 4.2 percent . The number of reservoirs (i.e., Rend Lake, Crab Orchard Lake, etc.) on both the Big Muddy and its tributaries affect the concentrations of parameters at this station.

Big Muddy River (N 12)	Inorganic N	T Phosphorus	TSS
With max flow	1,389,830 Kg·year^{-1}	445,435 Kg·year^{-1}	129,671,539 Kg·year^{-1}
Without max flow	1,406,711 Kg·year^{-1}	428,670 Kg·year^{-1}	124,157,722 Kg·year^{-1}

The response of the calculated loads to the removal of the maximum recorded flow events from the regression equation was mixed due to the relationship between the flow and concentration of the parameter at the three stations. On combinations where there was a significant correlation (at $p<0.05$) between flow and concentration, removal of the high flow resulted in a decrease in estimated loads of 70 percent or more. These included total suspended solids and total phosphorus on Bear Creek, and total suspended solids on the Vermilion River (Table 5-3). Because of the effects that samples collected during record high flow events had on Bear Creek and the Vermilion River loads, the samples on those dates were removed from the regression equations. Record high flows on the Big Muddy River were left in the data set as they had little effect on the outcome. On the remaining streams, removal of the highest sampled flow event had no significant effect on the regression equation results and were therefore left in.

The regression coefficients from the Cohn [c] method, results of an F-test to determine if the regression model was significant, coefficients of determination (r^2) values, which indicate the fit of the regression model and the results of a *t-test* to evaluate the significance of each of the seven regression coefficients are presented in Appendix D. The F-values on all the equations exceeded the F-critical value (2.08 at the $p \leq 0.05$ level for v1 = 7 and v2 = 125; Snedecor and Cochran, 1980) indicating that all the equations could be used with some assurance of validity. Coefficients of determination (C.O.D.) values for inorganic nitrogen ranged from 0.134 on Henderson Creek to 0.798 on the Green River. For total phosphorus, C.O.D. values ranged from 0.109 on the Illinois River at Valley City to 0.633 the Vermilion River near Danville. Total suspended solids C.O.D. values were also lowest on the Illinois River, 0.135, but were highest on

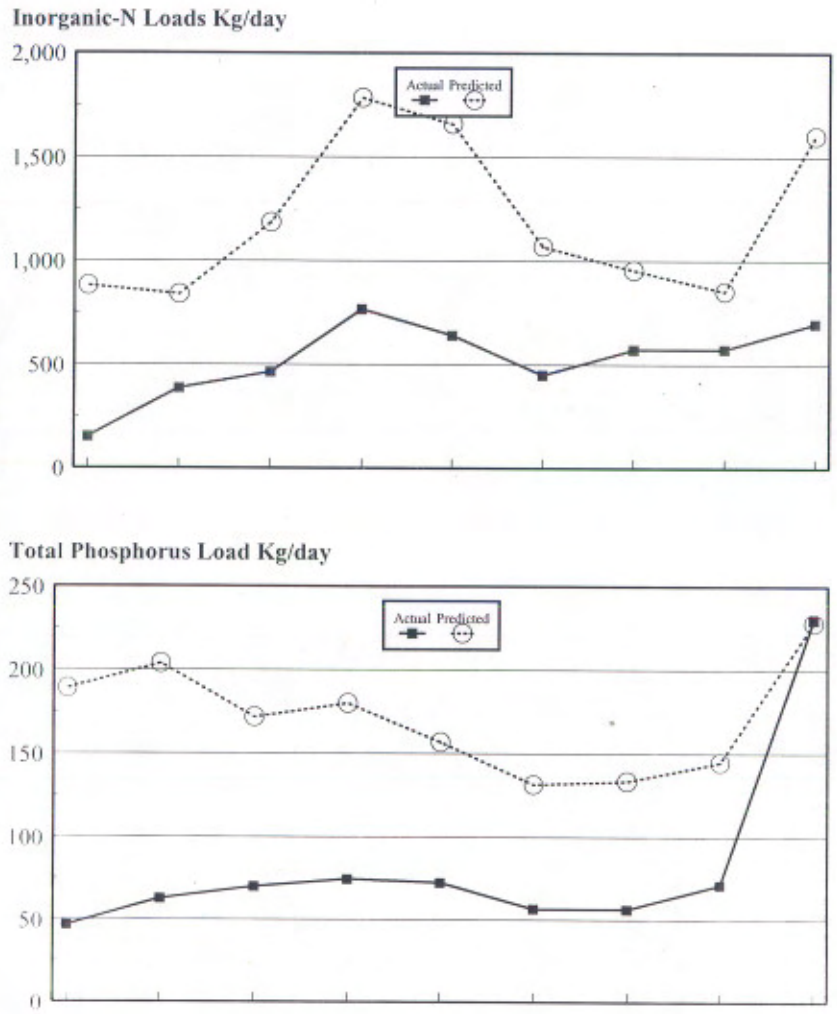

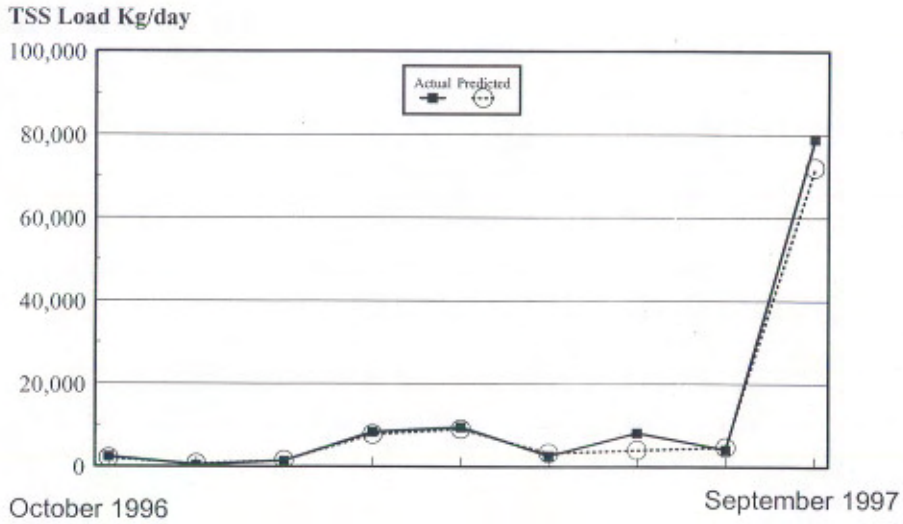

Figure 5-6. Comparison of load data from the Illinois River (D 32) for the 1997 water year.

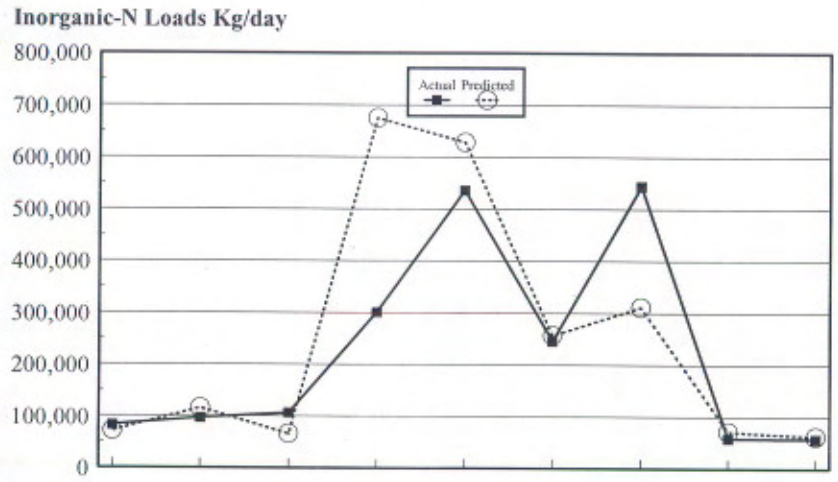

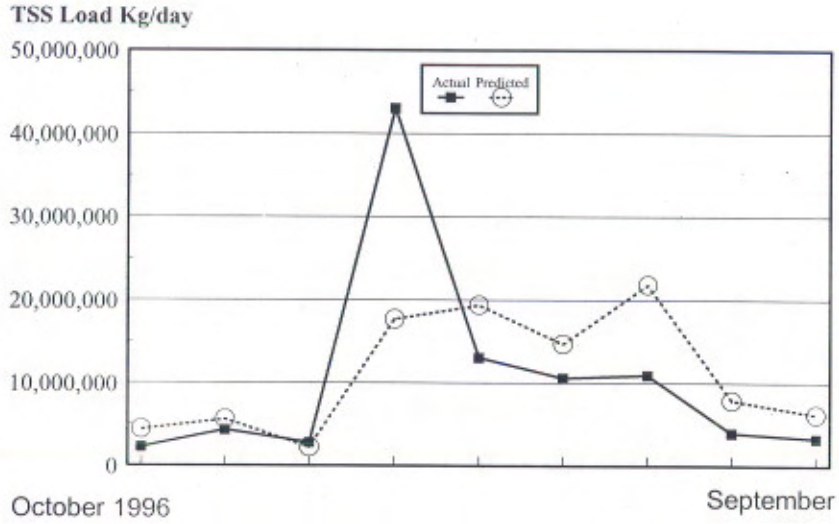

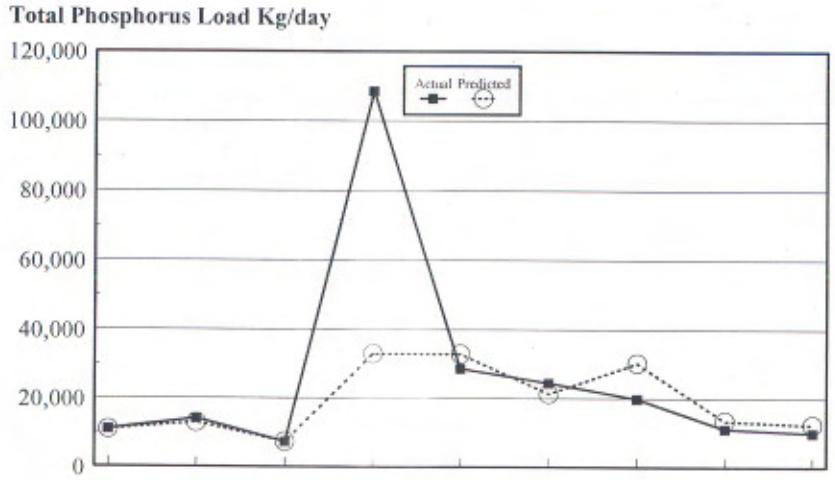

Figure 5-7. Comparison of load data from the Vermilion River (BP 01) for the 1997 water year.

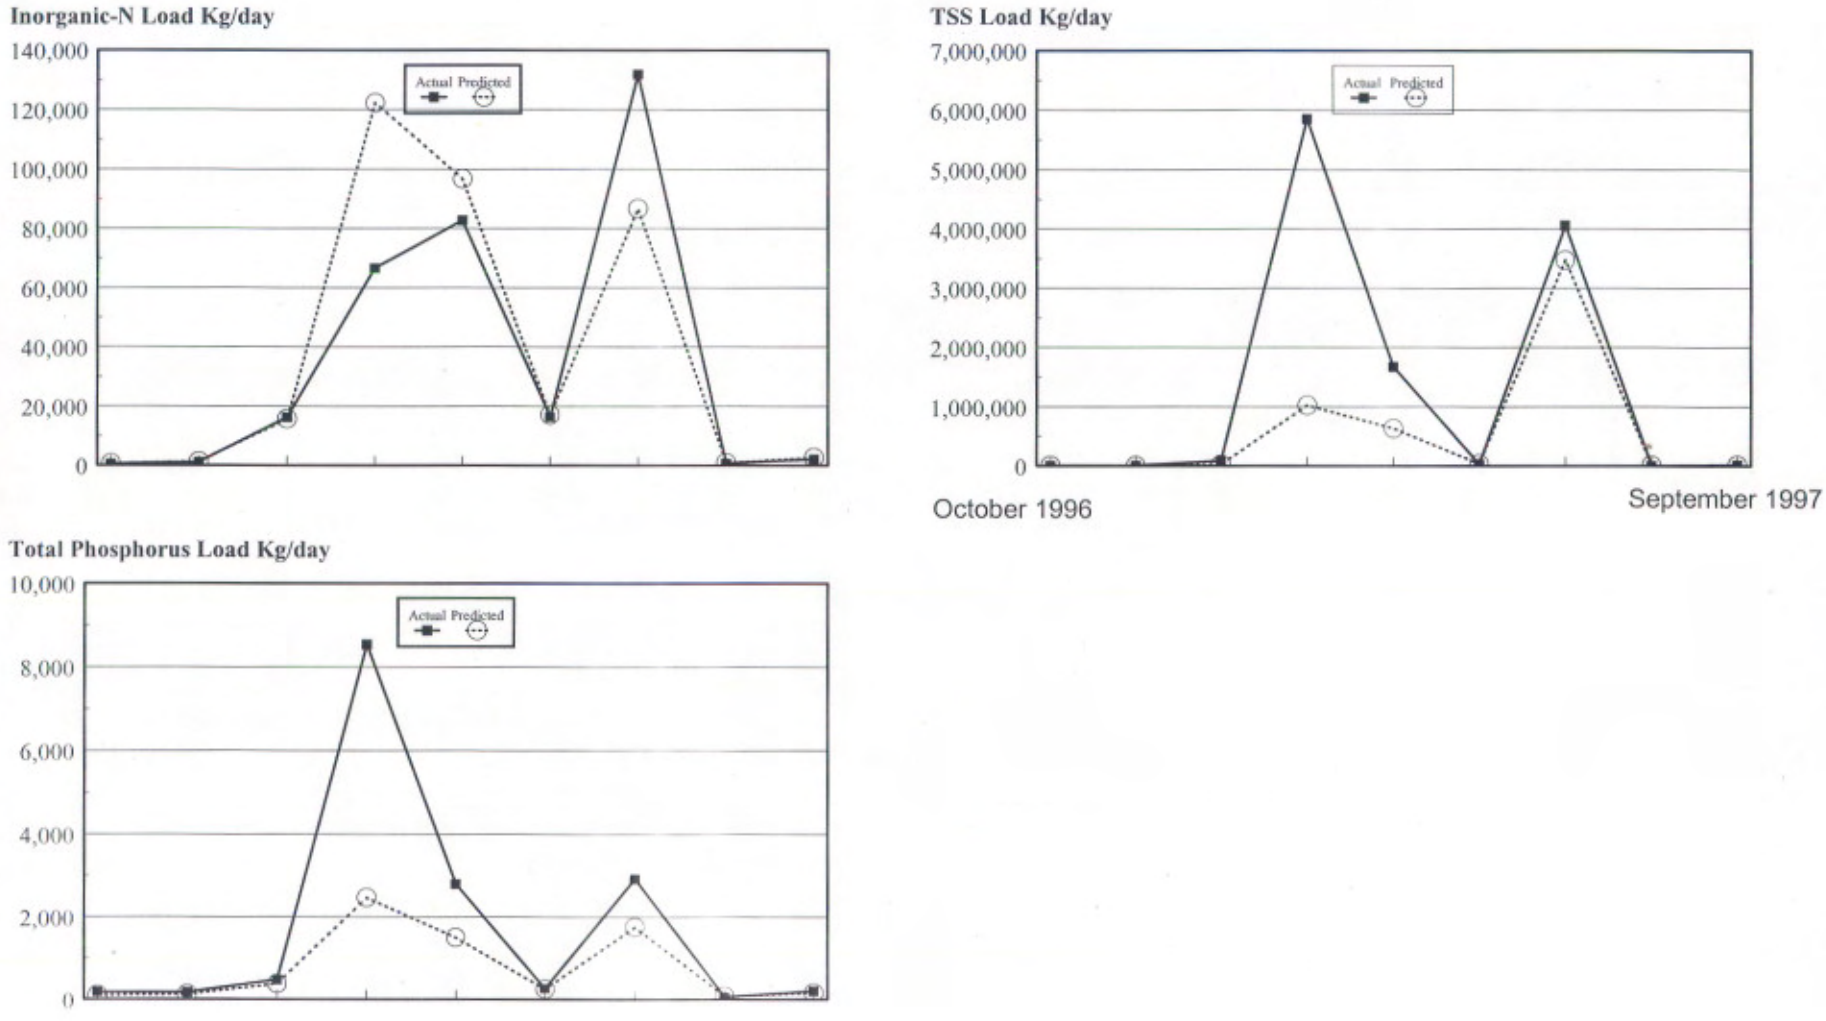

Figure 5-8. Comparison of load data from the Rock River (P 04) for the 1997 water year.

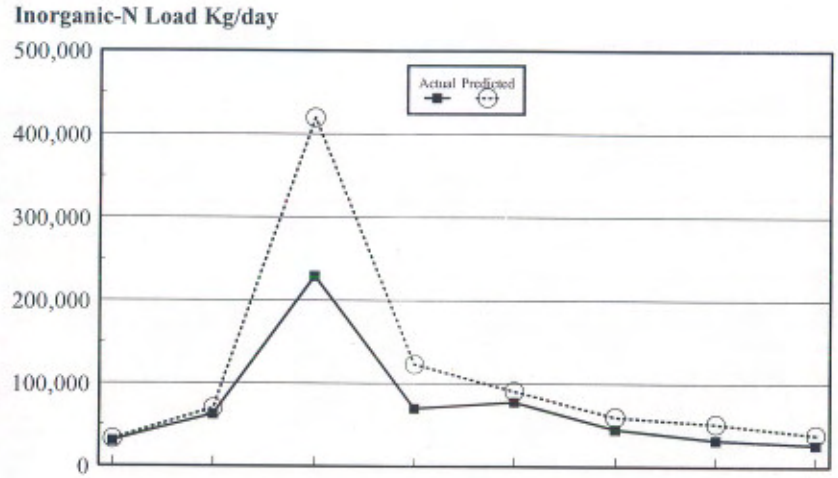

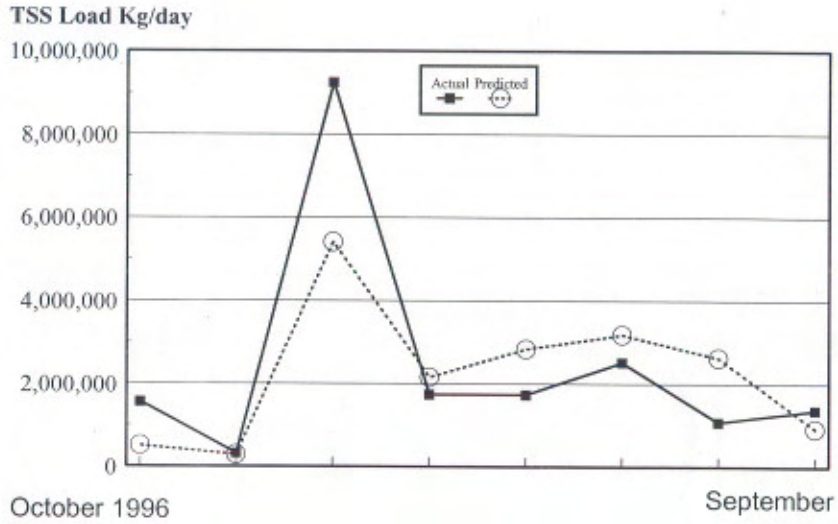

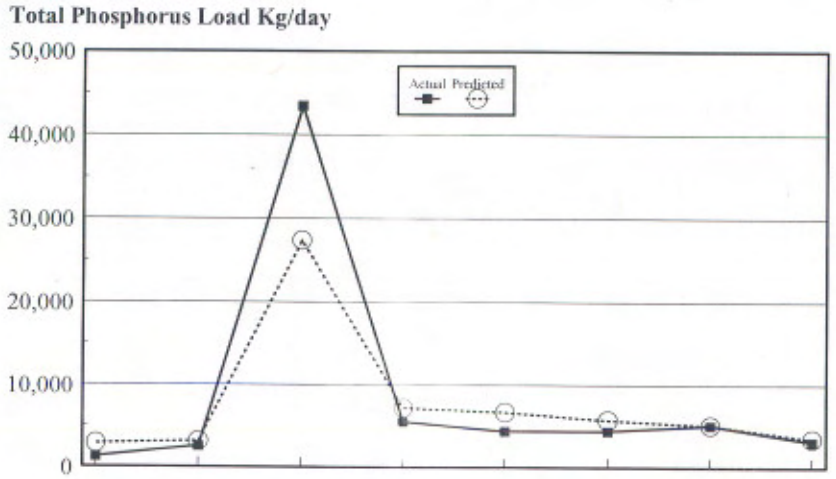

the Green River, 0.727. Higher C.O.D. values indicate a better fit of the regression model.

Results of the comparison between 1997 water year loads and those predicted by the regression equation are summarized in Table 5-4. Results of the paired *t-test* indicated that only three predicted loads, inorganic nitrogen and phosphorus loads on Richland Creek and total phosphorus loads on the Cache River, were significantly different from the actual loads at the $p<0.05$ level. Graphs of the comparisons indicated that predicted values were higher than the actual loads at these stations (Figure 5-5). At the other stations, statistically, the predicted loads on sampling dates for the 1997 water year were not significantly different from the actual loads on those dates. (Figures 5-6 through 5-8).

Flux of nutrients from Illinois to the Mississippi River

Although the strength of the regression equations was variable from site to site, a decision was made to calculate loads and yields of inorganic nitrogen, total nitrogen, total phosphorus and total suspended solids by station for the 1996 water year and the 16 year mean based on the Cohn [c] regression models (Tables 5-5 and 5-6) to facilitate comparisons with the national assessment. Results of the nutrient loads from stations within the same watershed were then combined and increased by the ratio of the total drainage area, to estimate overall export from the state of Illinois to both the Mississippi River (Table 5-7) and the Ohio River basin (Table 5-8). In general, loads follow a pattern of increasing on main stem rivers the further one goes downstream in the watershed, due primarily to increased flows.

Results of the loadings using the regression model were similar to those presented in the baseline loading section of this report in regard to the distributions of where the loads were coming from. The Illinois River watershed was the primary source of inorganic nitrogen (72 percent) total nitrogen (69.4 percent) and phosphorus (56 percent) loadings to the Mississippi River from the state of Illinois followed by the Rock River basin (18 percent for inorganic N, 19 percent for total nitrogen and 19 percent for total phosphorus). The Kaskaskia River was the third largest single source of inorganic nitrogen (4.2 percent), total nitrogen (4.6 percent) and phosphorus (13 percent) loadings to the Mississippi River from the state of Illinois. Loads of inorganic nitrogen and phosphorus from the smaller tributaries, when combined, accounted for 5.7 percent and 11.2 percent of the total export from Illinois to the Mississippi River respectively.

When compared with the Mississippi River at Keokuk, Iowa, loads of total nitrogen, inorganic nitrogen and phosphorus from the Rock River basin on average, were equivalent to approximately 17 percent, 15 percent and 15 percent respectively of the total load. When loads from the other smaller tributaries in the northern third of Illinois were combined with the loads from the Rock River, Illinois contribution was equivalent to 20 percent of the inorganic nitrogen load and 18 percent of the phosphorus load in the Mississippi River at Keokuk, Iowa.

Export from the portion of Illinois draining into the Mississippi River was compared with loads calculated for the Mississippi River at Thebes, Illinois. The 16 year mean flux of inorganic nitrogen from Illinois was equivalent to 35.3 percent of the 16 year mean annual load on the Mississippi River at Thebes, Illinois. Fluxes of total nitrogen were limited to four of the basins during the 16 year period of record, and were comprised primarily of inorganic nitrogen on the Rock River (74.7 percent), Illinois River (81.2 percent) and Kaskaskia River (70.7 percent) watersheds. In the Big Muddy River basin, inorganic nitrogen comprised less than half (44.3 percent) of the export of total nitrogen. Estimates of total nitrogen loads were made on streams where TKN data was not available based on the average of the ratio between inorganic nitrogen and total nitrogen loads on the watersheds where it was available. Based on this information, the export of total nitrogen from Illinois was equivalent to approximately 28 percent of the total nitrogen load to the Mississippi River at Thebes. The export of phosphorus from

Table 5-7 . Export of nutrients from Illinois to the Mississippi River; 16 year mean and 1996 water year based on the Cohn regression model and adjusted for watershed area. All values are in Kg·year^{-1}.

* note: total nitrogen data was not available at all stations

Illinois was equivalent to 20.3 percent of the total load at the Mississippi River at Thebes (Table 5-7). The export of inorganic nitrogen, total nitrogen and phosphorus from Illinois to the Mississippi River were lower during the1996 water year, than the 16 year mean. However, loads of those constituents on the Mississippi River at both Thebes, Illinois, and Keokuk, Iowa, were higher during the 1996 water year than the long term mean. Percentages assume that there was no loss of nitrogen or phosphorus due to transformation, respiration or settling out into sediments as it traveled downstream.

Flux of nutrients from Illinois to the Ohio River

Flux of inorganic nitrogen, phosphorus and total nitrogen from Illinois to the Ohio River during the 1996 water year and the 16 year mean based on the regression model are presented in Table 5-8. As with the Mississippi River watershed, the distribution of loads in the Ohio River watershed were similar to those in the baseline loading section of this report. The Vermilion River and Embarras River basins contributed the majority of the 16 year annual mean inorganic nitrogen load from Illinois (45.8 percent and 39.4 percent respectively). However, when total nitrogen loads were compared, the Little Wabash River and Vermilion River had approximately

Table 5-8. Export of nutrients from Illinois to the Ohio River basin; 16 year mean and 1996 water year based on the Cohn regression model and adjusted for watershed area. Values are in Kg·year^{-1}.

* note total nitrogen is lower than inorganic nitrogen due to the absence of TKN data at all stations.

equal values for the 1996 water year: 7,200,000 Kg/Year^{-1}. The makeup of the total nitrogen load from these two watersheds was significantly different. The majority of the nitrogen flux from the Vermilion River basin was coming from inorganic nitrogen, primarily in the form of nitrates (99 percent). However, inorganic nitrogen made up only 36.5 percent of the total nitrogen flux in the Little Wabash River basin for the 1996 water year. The majority of nitrogen flux on the Little Wabash River came from organic nitrogen. Long term mean export from the two watersheds indicated that the Vermilion River basin typically has twice the nitrogen load as the Little Wabash River basin.

When compared with the Ohio River at Olmstead, the average total flux of inorganic nitrogen from the portion of Illinois which drains to the Ohio River basin over the 16 year period of record, was equivalent to 6.8 percent of the total load. Estimates of the percentage of total nitrogen load from Illinois were equivalent to approximately 6.4 percent of the total nitrogen load in the Ohio River. The total nitrogen load was estimated by basing the total nitrogen load from the Embarras River and Bonpas Creek watersheds as being similar to the ratio of inorganic to total nitrogen load on the Vermilion River. The ratio of inorganic nitrogen load to total nitrogen load from the Cache River was estimated to be similar to that of the Lusk Creek watershed. Mean phosphorus loads were highest on the Little Wabash River and Embarras River. The total flux of phosphorus from Illinois was equivalent to approximately 6.9 percent of the total on the Ohio River at Olmstead. These percentages assume that there was no loss of nitrogen or phosphorus due to transformation, respiration or settling out into sediments as it traveled downstream.

Yields

Yields of inorganic nitrogen, total nitrogen, total phosphorus and total suspended solids by station for the 1996 water year and the 16 year mean based on the regression model are presented in Table 5-6. Yields were also calculated on the large river stations based on their total drainage area.

Inorganic nitrogen yields on streams draining into the Mississippi River, were highest on two of the smaller tributaries, Edwards River and Henderson Creek exceeding 2,200 Kg·Km^{-1}·Yr^{-1} for the 16 year mean. Yields of inorganic nitrogen on the Illinois River were the third highest at 1,806 Kg·Km^{-1}·Yr^{-1} for the 16 year mean and were lower, 1,143 Kg·Km^{-1}·Yr^{-1}, during the 1996 water year. Yields of inorganic nitrogen on the Kaskaskia River and its tributary Silver Creek were less than 500 Kg·Km^{-1}·Yr^{-1} but were nearly three times higher on Richland Creek due to the influence of point source discharges. Inorganic nitrogen yields decreased from north to south on both the tributaries and the Mississippi River itself. Inorganic nitrogen yields on the Mississippi River decreased from 384 Kg·Km^{-1}·Yr^{-1} near Keokuk, Iowa, to 283 Kg·Km^{-1}·Yr^{-1} near Thebes, Illinois. Total nitrogen yields on the Mississippi River also decreased from 571 to 460 Kg·Km^{-1}·Yr^{-1} at the two stations respectively.

Mean yields of phosphorus over the 16 year period of record on tributaries to the Mississippi River ranged from 79 $Kg \cdot Km^{-1} \cdot Yr^{-1}$ on the Big Muddy River, to 442 $Kg \cdot Km^{-1} \cdot Yr^{-1}$ on Richland Creek. Phosphorus yields exceeded 150 $Kg \cdot Km^{-1} \cdot Yr^{-1}$ on the Edwards River, Henderson Creek, Bear Creek, Macoupin Creek and Silver Creek. Yields of phosphorus from the Rock River, Kaskaskia River and Illinois River were approximately 100 $Kg \cdot Km^{-1} \cdot Yr^{-1}$. On the Mississippi River mainstem, there was no significant differences between mean phosphorus yields over the 16 year period of record. Yields were 35 $Kg \cdot Km^{-1} \cdot Yr^{-1}$ at Keokuk, Iowa and 37 $Kg \cdot Km^{-1} \cdot Yr^{-1}$ at Thebes, Illinois.

Yields of inorganic nitrogen in the Ohio River watershed were substantially higher on the Vermilion River (2,974 $Kg \cdot Km^{-1} \cdot Yr^{-1}$) and Embarras River (1,611 $Kg \cdot Km^{-1} \cdot Yr^{-1}$), reflecting the higher nitrate concentrations in these two streams when compared with other Illinois streams in the Ohio River drainage. The higher nitrate concentrations in streams in east central Illinois probably affected inorganic nitrogen yields on the Wabash River at Hutsonville, Illinois, which were 1707 $Kg \cdot Km^{-1} \cdot Yr^{-1}$. Streams in Indiana are also sources of inorganic nitrogen to the Wabash River. For example, median nitrate concentrations in the White River basin ranged between 2 and 6 mg/L and were considered much higher than most other streams monitored in the United States (Fenelon, 1998). With the exception of the Little Wabash River, yields from Illinois tributaries to the Ohio River watershed were lower in 1996 than the 16 year mean. Yields of inorganic nitrogen on both the Ohio River and Wabash River were higher than the Mississippi River (Table 5-6).

In the Ohio River basin, mean phosphorus yields over the 16 year period of record ranged from 13 $Kg \cdot Km^{-1} \cdot Yr^{-1}$ on Lusk Creek to 264 $Kg \cdot Km^{-1} \cdot Yr^{-1}$ on the North Fork Embarras River. Yields of phosphorus on both the Ohio River and Wabash River were higher than the Mississippi River (Table 5-6).

Comparison of Loads by Method

Results of four different methods to calculate mean annual loads were compared against each other from the 21 interior stations: baseline load, flow weighted mean, Cohn [c] and Cohn [L]. As noted above, high flow events had a significant effect on calculated loads on Bear Creek and the Vermilion River, using the regression models. For this comparison, the high flow events were removed from the regression calculations but remained in the flow weighted and baseline loads. Relative percent differences (RPD) were based on the following formula: $RPD = (2 * (method_a - method_b))/(method_a + method_b)$.

The four methods resulted in significant differences in mean annual load estimates on some streams. Although (r^2) values on the Illinois River were relatively low for both total phosphorus and total suspended solids loads using the Cohn [C] method (0.109 and 0.135 respectively), indicating a poor fit of the regression model, annual mean estimates of loads based on the four methods were within ± 9 percent of each other. Annual mean load estimates on the

Rock River were also within ± 9 percent irregardless of which method was used to calculate them. The Green River was the next most consistent stream for comparison, with all of the mean annual loads being within ±14 percent. The closeness of the loading results on these three streams reflects, in part, the flow pattern shown in Table 5-3. These were the only three streams where high flow events (2*Qmean) accounted for less than 40 percent of the total flow volume. Chemical sampling at these stations also appeared to occur over a broader range of conditions when flows were at the upper portion of the hydrograph. This suggests that the method used to arrive at the estimated load, based on the available data, was not critical at these three stations.

Results of annual mean loads calculated using the flow weighted averaging method and the Cohn [C] method were the most similar. Thirteen of the twenty-one stations had annual means that were within ± 10 percent of each other for inorganic nitrogen: Vermilion River, Embarras River, Little Wabash River, Lusk Creek, Cache River, Plum River, Rock River, Green River, Edwards River, Henderson Creek, Illinois River, Kaskaskia River and Silver Creek. For total phosphorus loads, 11 of the 21 stations were within ± 10 percent of each other: Vermilion River, Bonpas Creek, Little Wabash River, Rock River, Green River, Edwards River, Bear Creek, Illinois River, Kaskaskia River, Silver Creek, Richland Creek and Big Muddy River. For total suspended solids loads, 10 of the 21 stations were within ± 10 percent of each other: Lusk Creek, Cache River, Rock River, Green River, Henderson Creek, Bear Creek, Illinois River, Kaskaskia River, Silver Creek and the Big Muddy River.

When compared with baseline loads, loads using the Cohn [C] method were within ± 10 percent at eight of the 21 stations for inorganic nitrogen: Embarras River, Apple River, Rock River, Green River, Edwards Creek, Henderson Creek, Illinois River, and Macoupin Creek; nine stations for total phosphorus: Embarras River, Little Wabash River, Cache River, Plum River, Rock River, Green River, Illinois River, Cahokia Creek and Kaskaskia River; and five stations for total suspended solids: Little Wabash River, Apple River, Rock River, Henderson Creek and the Illinois River.

The largest percent of variation resulted on comparisons between the regression method using Cohn [L] with the other three methods. On the Apple River, Henderson Creek, Bear Creek, Richland Creek and Lusk Creek annual mean loads for inorganic nitrogen, total phosphorus and total suspended sediment, were between 100 and 130 percent less than those based on the regression method using concentrations (Cohn [C]). Similar results occurred when the Cohn [L] method was compared to the flow weighted averages and baseline loads (Table 5-10). The dissimilarity of the Cohn [L] method with the others may be a reflection of the flow regimen on these streams.

It is not clear how much the limitations of the chemical data influenced the results of the estimated annual loads using the various methods. Since there were a total of 5844 sampling days available, the chemical samples accounted for only 2.6 percent of the total. Comparing the regression models with their accompanying greater detail of analysis highlighted several facts about the data and uses of loading information in general. Fixed monitoring stations sampled on

a routine frequency, and therefore random to events such as floods and droughts, provide a good estimator of concentrations at different flow regimes. However, the effects of stream flow modifications (e.g., dams or reservoirs), highly variable flow regimens or where parameter concentrations are affected by point source discharges, require additional sampling to better characterize loads. In addition, the lack of correlation between the various forms of nitrogen and stream flow suggests that a flow weighted method may be more appropriate than a regression model to characterize these loads.

Table 5-10. Comparison of results from four methods to estimate loadings in Illinois streams.

CORE1 CORE Ambient - UASN + 720 Cyanide, 1002 Arsenic, 32730 Phenol, 951 Fluoride, 71900 Mercury, 940 Chloride, 945 Sulfate, 70508 Total Acidity, 410 Alkalinity, 625 Total Kjeldahl N.

CORE2 Water Organics - 39516 PCBS, 39330 Aldrin, 39380 Dieldrin, 39370 Total DDT, 39327 O, p DDE, 39320 p, p' DDE, 39315 o, p DDD, 39310 p, p' DDD, 39305 o, p DDT, 39300 p, p' DDT, 39350 Total Chlordane, 39065 Chlordane trans isomer, 39068 Nonachlor cis isomer, 39071 Nonachlor trans isomer, 39390 Endrin, 39480 Methoxychlor, 39337 Hexachlorocyclohexane, 39340 gamma BHC-Lindane, 39700 Hexachlorobenzene, 39032 Pentachlorophenol, 39062 Chlordane cis isomer.

PEST1 Pesticide Subnetwork - 77825 Alachlor, 39630 Atrazine, 81410 Butylate, 39640 Captan, 81403 Chloropyrifos, 81757 Cyanazine, 39570 Diazinon, 81294 Fonofos, 39530 Malathion, 39600 Methyl Parathion, 39356 Metolachlor, 81408 Metribuzin, 46314 Phorate, 82088 Terbufos, 81284 Trifluralin + CORE2.

IND01 Industrial Subnetwork - 32106 Chloroform, 32101 Dichlorobromomethane, 32105 Chlorodibromomethane, 32104 Bromoform, 34423 Methylene Chloride, 34501 1,1-Dichloroethylene, 34496 1,1-Dichloroethane, 34546 Trans-1,2-Dichloroethylene, 34531 1,2-Dichloroethane, 34506 1,1,1-Trichloroethane, 32102 Carbon Tetrachloride, 39180 Trichloroethylene, 34475 Tetrachloroethylene, 34301 Chlorobenzene, 34716 Dichlorobenzene (total), 78124 Benzene, 78131 Toluene, 78113 Ethylbenzene, 81551 Xylenes, 77093 CIS-1,2-Dichloroethylene.

Appendix B. Summary of Illinois EPA ambient water quality data for ammonia, nitrates, TKN, total and dissolved phosphorus, total and volatile suspended solids. October 1980 through September 1996.
