## INTRODUCTION

Since October 1985, the Illinois EPA has routinely monitored streams throughout Illinois for commonly used herbicides and pesticides. Analysis has included seven herbicides: alachlor, atrazine, butylate, cyanazine, metolachlor, metribuzin and trifluralin; seven organophosphate insecticides: chlorpyrifos, diazinon, fonofos, malathion, methyl parathion phorate and terbufos; and one fungicide: captan. In addition, organochlorine pesticides, which have been banned (or severely limited in use), along with polychlorinated biphenyls (PCBs) were included as part of the analysis. These compounds included aldrin, dieldrin, total DDT and its isomers, total chlordane as isomers, endrin, methoxychlor, alpha-BHC, gamma-BHC (lindane) hexachlorobenzene and pentachlorophenol (PCP). Initially a 30 station subnetwork was established within the existing 211 station ambient water quality monitoring network (AWQMN) operated by the Illinois EPA (Appendix A). Sampling occurred approximately five times per water year (October through September). Goals included characterizing pesticide concentrations within selected locations, characterizing seasonal variations, and developing a baseline dataset for looking at long term trends in pesticide concentrations. The results of the initial three years were presented in a report by Moyer and Cross (1990) which also included results from the intensive sampling of storm events during May 1989, on Macoupin Creek (DA 09) and Spring Creek (EL 01). Since that initial report, several changes have occurred to the original pesticide monitoring subnetwork (PMN). The purpose of this report is to document changes and summarize the results to date.

As stated above, the PMN was initially comprised of 30 stations with the goal that four of these would be from urban or non-agricultural areas and the rest in the predominantly agricultural part of the state. Sampling occurred five times per year, once in the summer, fall and winter and twice in the spring. Beginning with the 1991 water year (i.e., October 1991) sampling was reduced to three times per year to reflect the periods of preapplication, application, and post application (Figure 1). In 1996, the Illinois EPA began a five year basin sampling rotation with the goal of assessing all the major drainage basins in the state once every five years. As part of that program, it was seen as desirable to be able to better quantify pesticides levels within the watersheds. Because of this, the stations changed from the original network to reflect the five year basin rotation. However, five of the original stations: Macoupin Creek (DA 06), Bay Creek (KCA 01), Bear Creek (KI 02), Mackinaw River (DK 13) and the Sangamon River (E 28), have been sampled continuously over the 14 years. Four additional streams have 13 years of data including the La Moine River (DG 01 and DG 04), Spoon River (DJ 08), Green River (PB 04) and Elkhorn Creek (PH 16).

## RESULTS

A total of 1,806 stream surface water samples collected by the Illinois EPA were analyzed for currently used pesticides between October 1985 and December 1998. Table 1 and Figure 2 illustrate the summary statistics for the statewide data set along with the detection levels of the pesticides monitored. Atrazine was the most commonly detected herbicide and was present in 71.4 percent of the samples, followed by metolachlor (54.8%), cyanazine (49.5%), alachlor (44.4%), metribuzin (12.6%) and trifluralin (6.7%). Dicamba had a detection rate of

13.1 percent however, it was only analyzed in 84 samples. Terbufos was detected in 6 of 1,802 samples and the remaining pesticides were detected in at least one sample. For comparison, a summary of pesticides applied to corn and soybeans in 1998 is provided in Table 2. Atrazine was the most widely used herbicide on fields planted in corn and was applied to 78 percent of the acres. Glyphosphate (Roundup) was the most commonly used herbicide on fields planted with soybeans and was applied on 59 percent of those acres. However, glyphosphate was not included in the compounds analyzed.

Organochlorine and PCB concentrations analyzed along with organophosphate pesticides from stream surface water samples are summarized in Table 3. Sample numbers are somewhat higher ( $n \sim 400$  samples) due to the fact that these compounds were collected as part of other monitoring subnetworks over the same October 1985 to December 1998 time period. With the exception of pentachlorophenol (PCP) detection rates were less than 0.4 percent. Detections of PCP, a wood preservative, occurred in 21.1 percent of the samples. However, in 1997 the minimum reported value was raised from 0.01  $\mu\text{g/L}$  to 0.10  $\mu\text{g/L}$  as a result of a change in analytical method. Concentrations and detections of PCP appeared to be declining over time before this change (Figure 3). It is interesting to note that decline also corresponds with the elimination of sampling from the Des Plaines River (G 15) after 1991, where PCPs were detected in 73.3 percent of the samples.

Data from individual stations for the seven most commonly detected pesticides: alachlor, atrazine, cyanazine, metolachlor, metribuzin, trifluralin and PCP are presented in Appendix B. Figures 4 through 8 are box plots illustrating the range of concentrations by water year for the five most commonly detected organophosphate pesticides based on the entire dataset. The box plots represent the 10<sup>th</sup> (bottom tail), 25<sup>th</sup> (bottom of box), 75<sup>th</sup> (top of box), and 90<sup>th</sup> (top tail) percentiles of the data. The bottom tail generally does not show because the 25<sup>th</sup> percentile (bottom line of the box) fell into the minimum reporting level for all the parameters. Likewise, no graph was included for trifluralin because the minimum reported level (0.01  $\mu\text{g/L}$ ) was found in more than 90% of the samples. Figures 9 through 12 are box plots of alachlor, atrazine, cyanazine and metolachlor by season. Seasons were defined as: Fall (October, November, December), Winter (January, February, March), Spring (April, May, June) and Summer (July, August, September). Again, trifluralin and metribuzin were not included because the low rates of detection resulted in no significant seasonal variation which could be illustrated. Figure 13 illustrates the median concentration of atrazine, metolachlor and cyanazine by watershed.

Trend analysis was one of the original goals of the network. However, due to the changes in sampling frequency, station selection, the effects of seasonality (flow and rainfall) and the large number of values at the reporting limits, a detailed evaluation of trends is not included in this report. A cursory look at atrazine (since it had the highest percentage of values above the minimum reporting level) revealed some patterns. Stations were limited to those with 13 or 14 years of data and included 10 of the original PMN stations. An ANOVA (analysis of variance) was used to test if the differences in mean atrazine concentrations between years, months and stations was significant. The null hypothesis ( $H_0$ ) was that there was no significant difference at the  $p \leq 0.05$  level. Although the ANOVA can indicate that a significant difference exists between the means, it cannot indicate which means differ from one another. In order to further delineate between years, months and stations, a TUKEY test was used to evaluate the

significance of differences (SYSTAT, 1997). These comparisons were run on the raw data. Box plots comparing stations are shown in Figure 14. Results of the statistical tests are provided in Appendix C and can be summarized as follows:

**YEARS:** The comparison indicated that there were no statistically significant differences between years. This suggests no widespread increasing or decreasing trend in atrazine concentration over time in Illinois streams.

**MONTHS:** Concentrations of atrazine from samples collected during the months of May and June were statistically significantly higher than the other months but were not significantly different from each other. Since the months of February and December consisted of only five samples each, their results were disregarded for this comparison.

**STATIONS:** Bay Creek (KCA 01) and Bear Creek (KI 02) were similar in mean atrazine concentrations and were significantly higher than the Spoon River (DJ 08), Mackinaw River (DK 13), Sangamon River (E 28) and the Green River (PB 04). Bear Creek was also significantly higher than the La Moine River (DG 04). Concentrations of atrazine in Macoupin Creek (DA 06), the La Moine River (DG 01) and Elkhorn Creek (PH 16) were not significantly different from the other stations.

## **RECOMMENDATIONS**

1. Breakdown products of commonly used pesticides should be analyzed for. The USGS has found that these products are more frequently detected than the parent compounds.
2. Due to its widespread use, Glyphosphate (Roundup) should be added to the routine parameter list.
3. Currently, sampling is limited to 30 stream stations statewide per year. In order to better utilize this, a small number of stations (n=5) should be sampled on the same rotation as the other AWQMN samples (i.e. once every 6 weeks) to evaluate long term trends. These should include Lusk Creek (AK 02), the Little Wabash River near Louisville (C 19), the Des Plaines River at Schiller Park (G 15), Bear Creek (KI 02) and the Sangamon River at Monticello (E 28). The remaining 25 stations would continue to be sampled 3 times per year at AWQMN stations in the intensive basin rotation.
4. A follow up report should be conducted in 5 years to evaluate long term trends.

1. The first part of the document discusses the importance of maintaining accurate records of all transactions. This is crucial for ensuring the integrity of the financial statements and for providing a clear audit trail. The document emphasizes that every entry should be supported by appropriate documentation, such as invoices, receipts, and contracts.
