TMDL Development for the DuPage River/Salt Creek Watershed, Illinois

This file contains the following documents:

- 1) U.S. EPA Approval Letter and Decision Document for the Final TMDL Report
- 2) TMDL Report

THIS PAGE LEFT INTENTIONALLY BLANK

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY REGION 5 77 WEST JACKSON BOULEVARD CHICAGO, IL 60604-3590

REPLY TO THE ATTENTION OF:

SEP 0 5 2019

WW-16J

Sanjay Sofat, Chief Bureau of Water Illinois Environmental Protection Agency P.O. Box 19276 Springfield, Illinois 62794-9276

Dear Mr. Sofat:

The U.S. Environmental Protection Agency has conducted a complete review of the final Total Maximum Daily Loads (TMDLs) for fecal coliform, chloride, and dissolved oxygen-demanding substances for the DuPage River and Salt Creek watersheds, including supporting documentation and follow up information. The waterbodies are located in northeastern Illinois. The TMDLs submitted by the Illinois Environmental Protection Agency address the impaired Primary Contact and Aquatic Life Uses for the waterbodies.

The TMDLs meet the requirements of Section 303(d) of the Clean Water Act and EPA's implementing regulations at 40 C.F.R. Part 130. Therefore, EPA hereby approves Illinois's eighteen TMDLs for fecal coliform, chloride, and dissolved oxygen-demanding substances as noted in the enclosed decision document. The statutory and regulatory requirements, and EPA's review of Illinois's compliance with each requirement, are described in the enclosed decision document.

We wish to acknowledge Illinois's effort in submitting these TMDLs and look forward to future TMDL submissions by the State of Illinois. If you have any questions, please contact Ms. Candice Bauer, Acting Chief of the Watersheds and Wetlands Branch, at 312-353-2106.

Sincerely,

Junda Holst

Joan M. Tanaka Acting Director, Water Division

Enclosure

cc: Abel Haile, IEPA

TMDL: DuPage River and Salt Creek Watersheds 2, IllinoisDate:SEP 0 5 2019

DECISION DOCUMENT FOR THE APPROVAL OF THE DUPAGE RIVER AND SALT CREEK 2, IL TMDL

Section 303(d) of the Clean Water Act (CWA) and EPA's implementing regulations at 40 C.F.R. Part 130 describe the statutory and regulatory requirements for approvable TMDLs. Additional information is generally necessary for EPA to determine if a submitted TMDL fulfills the legal requirements for approval under Section 303(d) and EPA regulations, and should be included in the submittal package. Use of the verb "must" below denotes information that is required to be submitted because it relates to elements of the TMDL required by the CWA and by regulation. Use of the term "should" below denotes information that is generally necessary for EPA to determine if a submitted TMDL is approvable. These TMDL review guidelines are not themselves regulations. They are an attempt to summarize and provide guidance regarding currently effective statutory and regulatory requirements relating to TMDLs. Any differences between these guidelines and EPA's TMDL regulations should be resolved in favor of the regulations themselves.

1. Identification of Waterbody, Pollutant of Concern, Pollutant Sources, and Priority Ranking

The TMDL submittal should identify the waterbody as it appears on the State's/Tribe's 303(d) list. The waterbody should be identified/georeferenced using the National Hydrography Dataset (NHD), and the TMDL should clearly identify the pollutant for which the TMDL is being established. In addition, the TMDL should identify the priority ranking of the waterbody and specify the link between the pollutant of concern and the water quality standard (see Section 2 below).

The TMDL submittal should include an identification of the point and nonpoint sources of the pollutant of concern, including location of the source(s) and the quantity of the loading, e.g., lbs/per day. The TMDL should provide the identification numbers of the NPDES permits within the waterbody. Where it is possible to separate natural background from nonpoint sources, the TMDL should include a description of the natural background. This information is necessary for EPA's review of the load and wasteload allocations, which are required by regulation.

The TMDL submittal should also contain a description of any important assumptions made in developing the TMDL, such as:

(1) the spatial extent of the watershed in which the impaired waterbody is located;(2) the assumed distribution of land use in the watershed (e.g., urban, forested, agriculture);

(3) population characteristics, wildlife resources, and other relevant information affecting the characterization of the pollutant of concern and its allocation to sources;

(4) present and future growth trends, if taken into consideration in preparing the TMDL

(e.g., the TMDL could include the design capacity of a wastewater treatment facility); and

1

(5) an explanation and analytical basis for expressing the TMDL through *surrogate measures*, if applicable. *Surrogate measures* are parameters such as percent fines and turbidity for sediment impairments; chlorophyll <u>a</u> and phosphorus loadings for excess algae; length of riparian buffer; or number of acres of best management practices.

Comment:

Location Description: The Illinois Environmental Protection Agency (IEPA) developed TMDLs for fecal coliform, chloride, and dissolved oxygen (DO) demanding substances for impaired waters in the DuPage River and Salt Creek (DRSC) watersheds in north-eastern Illinois (Table 1 of this Decision Document). The DRSC watersheds are located in Cook, DuPage, and Will Counties. Table 1 of this Decision Document lists the waterbodies addressed by this TMDL.

Segment ID	Segment Name	Designated use	Pollutant Addressed
IL_GB-11	DuPage River	Aquatic Life	Chloride
		Primary Contact	Fecal Coliform
IL_GB-16	DuPage River	Aquatic Life	DO Demanding Substances (TP*, CBOD**, Ammonia)
		Primary Contact	Fecal Coliform
IL_GBK-05	West Branch DuPage River	Primary Contact	Fecal Coliform
IL_GBK-09	West Branch DuPage River	Primary Contact	Fecal Coliform
IL_GBK-14	West Branch DuPage River	Aquatic Life	DO Demanding Substances
		Primary Contact	Fecal Coliform
IL_GBKA	Spring Brook	Aquatic Life	DO Demanding Substances
		Primary Contact	Fecal Coliform
IL-GBKA-01	Spring Brook	Primary Contact	Fecal Coliform
IL_GBL-10	East Branch DuPage River	Primary Contact	Fecal Coliform
IL_GL-09	Salt Creek	Primary Contact	Fecal Coliform
IL_GL-10	Salt Creek	Primary Contact	Fecal Coliform
IL_GL-19	Salt Creek	Primary Contact	Fecal Coliform
IL_GLA-02	Addison Creek	Primary Contact	Fecal Coliform

Table 1.	TMDLs	in th	e DRSC	watershed
----------	-------	-------	--------	-----------

* - TP = Total Phosphorus

**- CBOD = Carbonaceous Biochemical Oxygen Demand, the measurement of oxygen demand due to organic material in water

The DRSC watershed is approximately 335,000 acres in size. The two main waterbodies (DuPage River and Salt Creek) are separate watersheds. The DuPage River begins as the East Branch and West Branch of the DuPage River, which merge to form the mainstem DuPage River. The DuPage River flows south into the Des Plaines River near Channahon, Illinois (Figure 1 of the TMDL). Salt Creek begins in Cook County, flows south into the Des Plaines River a few miles south of Channahon to form the Illinois River.

Significant alteration of the drainage in the watersheds has occurred over the last 100 years. Numerous dams have been built in the watersheds, both altering flows and preventing fish migration (Section 3.6 of the TMDL). Some of the dams have been removed or modified. The United States Geological Survey (USGS) operates several gages in the watersheds, as noted on Figure 9 of the TMDL. Review of the gage data indicates that the river systems are effluentdominated in mid-range to low flows.

IEPA identified several approved TMDL projects in the watersheds (Table 2 of the TMDL). In 2004, TMDLs were developed for the East Branch DuPage River (chloride, ammonia, CBOD), West Branch DuPage River (chloride), and Salt Creek (chloride, ammonia, CBOD, volatile suspended solids). The TMDLs addressed in this Decision Document followed up on watershed monitoring performed as part of the implementation of the 2004 TMDLs.

Distribution of land use: The land use for the DuPage River watershed is mainly urbanized in nature, with a small portion as agricultural (Table 2 of this Decision Document). The Salt Creek watershed is almost completely urbanized. Tables 3 and 4 and Figure 4 of the TMDL contain additional details on the land use in the watersheds. Both watersheds are highly populated; over 4.8 million people live in the two watersheds (Section 3.4 of the TMDL).

Land Use	DuPage River	DuPage River		Salt Creek		
	%	acres	%	acres		
Agriculture	14	32,218	<1	234		
Developed	75	183,058	93	87,488		
Forest	4	10,268	3	2,689		
Other	7	15,457	<4	4,431		
Total	100	241,001	100	94, 842		

Table 2: Land use in the DRSC Watersheds

Problem Identification:

The pollutants of concern are fecal coliform, low DO (DO-demanding substances), and chloride (Table 1 of this Decision Document).

<u>Fecal coliform</u>: The waterbodies identified in Table 1 of this Decision Document as being addressed for fecal coliform all exceeded the IEPA fecal coliform water quality standard (WQS), both the single-sample maximum and the geometric mean (Table 13 of the TMDL).

<u>DO</u>: Segment GB-16 (West Branch DuPage River) has been monitored for DO for several years, both discrete sampling and continuous monitoring (Section 5.1.2 of the TMDL). Results of the monitoring indicate that the waterbody exceeds the lower range of the DO standard during the later parts of the summer (Figures 22 and 23 of the TMDL). The DuPage River Salt Creek Workgroup (DRSCW) performed monitoring of Segments GBKA and GBK-14 in August of 2016. Monitoring results indicate the DO water quality standard is not being met.

<u>Chloride:</u> IEPA identified one segment (GB-11) as impaired for chloride (Section 5.1.4 of the TMDL). Water quality data indicted five exceedences out of 366 sampling observations between 1977 and 2010 (Table 16 and Figure 27 of the TMDL).

Pollutant:

Fecal coliform: Bacteria exceedances can negatively impact recreational uses (fishing, swimming, wading, boating, etc.) and public health. At elevated levels, bacteria may cause illness within humans who have contact with or ingest bacteria-laden water. Recreation-based contact can lead to ear, nose, and throat infections, and stomach illness.

<u>DO</u>: IEPA identified three segments as demonstrating degraded oxygen concentrations within the water column. Low dissolved oxygen concentrations can negatively impact aquatic life use. The decrease in dissolved oxygen can stress benthic macroinvertebrates and fish. Elevated levels of oxygen-consuming pollutants, such as ammonia, and CBOD, can reduce dissolved oxygen in the water column, and cause large shifts in dissolved oxygen and pH throughout the day. Excessive amounts of nutrients such as phosphorus can stimulate plant and algal growth, which can negatively impact DO levels in a waterbody as well. Shifting chemical conditions within the water column may stress aquatic biota (i.e., fish and macroinvertebrate species). In some instances, degradations in aquatic habitats or water quality have reduced fish populations or altered fish communities from those communities supporting sport fish species to communities which support more tolerant rough fish species.

<u>Chloride</u>: Chloride is essential for aquatic life to carry out a range of biological functions. However, high concentrations of chloride in the surrounding water can harm cellular osmotic processes in aquatic life. Excessive dissolved chlorides in water may stress aquatic species and prohibit the transport of needed molecules into the cell. Persistent elevated concentrations of chloride in the water may result in aquatic life such as fish, invertebrates and even some plant species becoming stressed and/or dying.

Priority Ranking:

The watershed was given priority for TMDL development due to the impairment impacts on the public value of the impaired water resource, and the timing as part of the Illinois basin monitoring process.

Source Identification (point and nonpoint sources):

Point Source Identification:

Fecal coliform: IEPA identified 39 individual point sources located in the DRSC watersheds (Section 5.3.1 and Table 18 of the TMDL). Of these 39 point sources, 31 are wastewater treatment facilities only (WWTFs). The remaining eight include Combined Sewer Overflow (CSO) systems, which can discharge mixed stormwater and sewage during high-flow events. IEPA also identified stormwater (Municipal Separate Storm Sewer System or MS4) as a potential source of bacteria in the watersheds.

Chloride: IEPA identified four NPDES-permitted facilities in Segment GB-11, which is impaired for chloride. WWTFs can discharge chloride as a result of deicing efforts as well as water softening discharge. IEPA also assigned allocations to the Illinois Department of Transportation (ILDOT) to address highway deicing efforts, as well as to MS4s in the watershed. (Table 27 of the TMDL).

DO substances: IEPA identified three WWTFs that discharge DO-demanding substances in Segment GB-16 (Lower DuPage River). Much of the organic material in wastewater is removed during the treatment process, but some amounts of organic material are discharged. When these substances decay in the stream, oxygen is consumed and the levels of dissolved oxygen drop. IEPA identified three pollutants: total phosphorus, total ammonia, and CBOD that need to be controlled in WWTF discharges. Although CSOs and MS4s can discharge DO-demanding substances, IEPA determined that the critical condition for low DO in the segment is during lowflow periods, when CSOs and MS4s are not significant contributors (Table 34 of the TMDL). The other two segments listed as impaired for low DO do not have any point source discharges.

<u>Nonpoint Source Identification</u>: The potential nonpoint sources for the DRSC watershed TMDLs are:

Fecal coliform:

Non-regulated stormwater runoff: Non-regulated urban stormwater runoff can add fecal coliform to the impaired waters. The sources of bacteria in stormwater include animal/pet wastes, and wildlife. IEPA noted that that much of the watersheds are covered by a MS4 permit, and therefore non-regulated stormwater runoff has limited impact in the watersheds.

Agricultural Operations: Runoff from agricultural lands may contain significant amounts of bacteria which may lead to impairments in the DuPage River watershed. There is limited agricultural land in the DuPage River watershed, and virtually none in the Salt Creek watershed.

Failing septic systems: IEPA noted that failing septic systems, where waste material can pond at the surface and eventually flow into surface waters or be washed in during precipitation events, are potential sources of bacteria. IEPA determined that while much of the watersheds are served by sewer systems, portions of the watersheds are not, and the potential for septic failure is possible.

Chloride:

Road salt runoff: IEPA determined that the major source of chloride loading to the DRSC watersheds is run-off from roadways containing road salt (Section 5.3.5 of the TMDL). Runoff from precipitation events as well as snowmelt can transport chloride into the waterbodies.

DO substances:

Agricultural Operations: IEPA noted that agricultural operations can generate DO-demanding substances that can run off farm fields and enter the waterbodies (Section 5. 4 of the TMDL). The use of fertilizers, field debris, and other organic matter can enter the waters, decompose, and use up the dissolved oxygen in the water column.

In-stream processes: Organic material can also enter the waters and settle to the streambed during the year, and then as flows are reduced during the late summer, decompose and scavenge oxygen. This is measured as sediment-oxygen demand (SOD). Nutrients can also stimulate the growth of algae and plants, which can consume oxygen during the night hours, causing significant daily swings in DO levels.

Non-regulated stormwater runoff: Non-regulated stormwater runoff can add DO-demanding substances to the impaired waters. Many of the same causes of bacteria loading also can contribute nutrients and organic material, such as pet wastes and wildlife.

Failing Septic Systems: Failing septics systems can contribute nutrients as well as bacteria to streams.

Population and future growth trends: The population for the watersheds is fairly significant; approximately 4.8 million people live in the two watersheds (Section 3.4 of the TMDL). The population is expected to continue to grow over the foreseeable future, particularly in the mainstem portion of the DuPage River in Will County. IEPA considered a reserve capacity to account for future growth, but determined that the loadings as calculated were sufficient (Section 6.3.3 of the TMDL). Future increases will require re-opening and possible modification of the TMDL. IEPA did determine allocations for two WWTFs based upon ongoing plant expansion, the Naperville-Springbrook WWTF (IL0034061) and the Bolingbrook WWTF (IL0069744) (Table 18 of the TMDL).

EPA finds that the TMDL document submitted by IEPA satisfies all requirements concerning this first element.

2. Description of the Applicable Water Quality Standards and Numeric Water Quality Target

The TMDL submittal must include a description of the applicable State/Tribal water quality standard, including the designated use(s) of the waterbody, the applicable numeric or narrative water quality criterion, and the antidegradation policy. (40 C.F.R. \$130.7(c)(1)). EPA needs this information to review the loading capacity determination, and load and wasteload allocations, which are required by regulation.

The TMDL submittal must identify a numeric water quality target(s) - a quantitative value used to measure whether or not the applicable water quality standard is attained. Generally, the pollutant of concern and the numeric water quality target are, respectively, the chemical causing the impairment and the numeric criteria for that chemical (e.g., chromium) contained in the water quality standard. The TMDL expresses the relationship between any necessary reduction of the pollutant of concern and the attainment of the numeric water quality target. Occasionally, the pollutant of concern is different from the pollutant that is the subject of the numeric water quality target (e.g., when the pollutant of concern is phosphorus and the numeric water quality target is expressed as Dissolved Oxygen (DO) criteria). In such cases, the TMDL submittal should explain the linkage between the pollutant of concern and the chosen numeric water quality target.

Comment:

Designated Use/Standards: Section 4.2 of the TMDL states that the DRSC watersheds are not meeting the General Use designation. The applicable water quality standards (WQS) for these waterbodies are established in Illinois Administrative Rules Title 35, Environmental Protection; Subtitle C, Water Pollution; Chapter I, Pollution Control Board; Part 302, Water Quality Standards, Subpart B for General Use Water Quality Standards. The portions of the WQS that

apply to the DRSC are General Use, specifically the Aquatic Life Use and Primary Contact Use (Section 4.2 of the TMDL).

Criteria: The applicable criteria are found in Table 3 of this Decision Document.

Table 3: WQSs	for the impaire	ed waters in the DRSC watersheds
Pollutant	Units	Criteria
Chloride	mg/L	500
Dissolved Oxygen	mg/L	For most waters (GBK-14 and GBKA):
		March-July >5.0 minimum and >6.0 as a 7-day mean
		Aug-Feb >3.5 minimum and >4.0 as a 7-day mean and
		>5.5 as a 30-day mean
		For enhanced waters (GB-16):
		March-July >5.0 minimum and >6.25 as a 7-day mean
		Aug-Feb >4.0 minimum and >4.5 as a 7-day mean and
		>6.0 as a 30-day mean
Fecal coliform	Count/100	May through October
	mL	$200^*, 400^{**}$

Table 3: WQSs for the impaired waters in the DRSC watersheds

* - geometric mean based upon a minimum of 5 samples in a 30 day period

** - not to be exceed by more than 10% of the samples in a 30 day period

Target: The water quality targets for these TMDLs are in Table 4 of this Decision Document.

<u>Fecal coliform</u>: IEPA used both portions of the WQS to determine loads. Allocations were developed for each bacteria-impaired segment based upon the 200 counts/100mL geometric mean and the 400 counts/100 mL single sample maximum (SSM) (Section 3 of this Decision Document).

Chloride: The IEPA used the numeric WQS for chloride of 500 mg/L as the TMDL target.

<u>DO</u>: IEPA determined that the DO instantaneous minimum portion of the WQS was most likely to be exceeded (Appendices E1-E3 of the TMDL). IEPA reviewed the DO data for the impaired segments, and noted that the waterbodies are meeting the "mean" portions of the DO criteria. Therefore, the modeling effort focused on the "minimum" portion of the WQS. The State determined that attaining the "minimum" portion of the criteria will result in attainment of the entire DO WQS (Appendices E1-E3 of the TMDL). The modeling effort undertaken by the State for Segment GB-16 was developed for early August, the critical time of year with the lowest DO conditions due to low in-stream flows and higher water temperatures. The corresponding DO instantaneous minimum target is >4.0 mg/L (Appendix E1 of the TMDL). For the other two segments, the modeling effort also was developed for early August. However, the State utilized a more conservative target of >5.0 mg/L (Appendices E2 and E3 of the TMDL).

As further discussed in Section 3 of this Decision Document, IEPA modeled the impacts of DOdemanding substances on the levels of DO in the streams. Several scenarios were investigated, and IEPA determined that total phosphorus, total ammonia, and CBOD were the three pollutants that needed to be controlled in Segment GB-16, and a more general pollutant of DO-demanding substances (DO-deficit; see Section 3 of this Decision Document for further explanation) need to be controlled in Segments GBK-14 and GBKA.

Pollutant	Target
Chloride	500 mg/L
DO*	>4.0 for GB-16
	>5.0 for GBK-14 and GBKA
Fecal coliform	200/400 counts/100 mL

 Table 4: TMDL targets for the DRSC Watersheds

* - Pollutants identified to address DO are total phosphorus, total ammonia, and CBOD for Segment GB-16 and DO-deficit for Segments GBK-14 and GBKA

EPA finds that the TMDL document submitted by IEPA satisfies all requirements concerning this second element.

3. Loading Capacity - Linking Water Quality and Pollutant Sources

A TMDL must identify the loading capacity of a waterbody for the applicable pollutant. EPA regulations define loading capacity as the greatest amount of a pollutant that a water can receive without violating water quality standards (40 C.F.R. §130.2(f)).

The pollutant loadings may be expressed as either mass-per-time, toxicity or other appropriate measure (40 C.F.R. §130.2(i)). If the TMDL is expressed in terms other than a daily load, e.g., an annual load, the submittal should explain why it is appropriate to express the TMDL in the unit of measurement chosen. The TMDL submittal should describe the method used to establish the cause-and-effect relationship between the numeric target and the identified pollutant sources. In many instances, this method will be a water quality model.

The TMDL submittal should contain documentation supporting the TMDL analysis, including the basis for any assumptions; a discussion of strengths and weaknesses in the analytical process; and results from any water quality modeling. EPA needs this information to review the loading capacity determination, and load and wasteload allocations, which are required by regulation.

TMDLs must take into account *critical conditions* for stream flow, loading, and water quality parameters as part of the analysis of loading capacity. (40 C.F.R. §130.7(c)(1)). TMDLs should define applicable *critical conditions* and describe their approach to estimating both point and nonpoint source loadings under such *critical conditions*. In particular, the TMDL should discuss the approach used to compute and allocate nonpoint source loadings, e.g., meteorological conditions and land use distribution.

Comment:

The approach utilized by the IEPA to calculate the loading capacity for the fecal coliform and chloride TMDLs is described in Section 6.1 of the TMDL. The TMDL summaries for fecal coliform and chloride are presented in Tables 5-29 of this Decision Document. For DO-demanding substances, the approach utilized by IEPA is described in Section 6.2 and

Appendices E1-E3 of the TMDL. The TMDL summaries for DO-demanding substances are presented in Tables 30-32 of this Decision Document.

<u>Fecal coliform and chloride</u>: For the bacteria TMDLs both the geometric mean of 200 counts/100 ml fecal coliform for five samples equally spaced over a 30-day period, and the SSM of 400 counts/100mL exceeded in no more than 10% of the samples per 30 days, were used to calculate the loading capacity of the TMDLs.

Typically loading capacities are expressed as a mass per time (e.g. pounds per day). However, for bacteria loading capacity calculations, mass is not always an appropriate measure because bacteria is expressed in terms of organism counts. This approach is consistent with the EPA's regulations which define "load" as "an amount of matter that is introduced into a receiving water" (40 CFR §130.2). To establish the loading capacities for the DRSC bacteria TMDLs, IEPA used Illinois's water quality standards for fecal coliform (200 cfu/100 mL). By calculating loads based upon both portions of the fecal coliform WQS, IEPA determined that the WQS will be met under either portion. A loading capacity is, "the greatest amount of loading that a water can receive without violating water quality standards." (40 CFR §130.2). Therefore, a loading capacity set at the WQS will assure that the water does not violate WQS. IEPA's fecal coliform TMDL approach is based upon the premise that all discharges (point and nonpoint) must meet the WQS when entering the water body. If all sources meet the WQS at discharge, then the water body should meet the WQS and the designated use.

For the chloride TMDL, the water quality target from Table 4 of this Decision Document (500 mg/L) was used to calculate the loading capacities.

Flow data from several USGS gages in the two watersheds were used to develop the Load Duration Curves (LDCs). Flow data was available for a number of years (Section 3.6 and Figure 9 of the TMDL). Daily stream flows are necessary to implement the LDC approach.

The LDCs were created by multiplying individual flow values by the WQS and then multiplying that value by a conversion factor. The resulting points are plotted onto a load duration curve graph. The LDC graphs for impaired waterbodies have flow duration interval (percentage of time flow exceeded) on the X-axis and pollutant loads (number of bacteria or pollutant mass per unit time) on the Y-axis. The fecal coliform LDC used fecal coliform measurements in millions of bacteria per day, while the chloride LDC used pounds per day. The curved line on a LDC graph represents the TMDL for the respective flow conditions observed at that location.

Pollutant values from the monitoring sites were converted to individual sampling loads by multiplying the sample concentration by the instantaneous flow measurement observed/estimated at the time of sample collection. The individual sampling loads were plotted on the same figure with the LDC (Section 7 of the TMDL).

The LDC plot was subdivided into five flow regimes; very high flows (exceeded 0-10% of the time), high conditions (exceeded 10-40% of the time), mid-range flows (exceeded 40-60% of the time), low conditions (exceeded 60-90% of the time), and very low flows (exceeded 90-100% of the time). LDC plots can be organized to display individual sampling loads and the

calculated LDC. Watershed managers can interpret these plots (individual sampling points plotted with the LDC) to understand the relationship between flow conditions and water quality exceedances within the watershed. Individual sampling loads which plot above the LDC represent violations of the WQS and the allowable load under those flow conditions at those locations. The difference between individual sampling loads plotting above the LDC and the LDC, measured at the same flow, is the amount of reduction necessary to meet WQS.

The strengths of using the LDC method are that critical conditions and seasonal variation are considered in the creation of the LDC by plotting hydrologic conditions over the flows measured during the recreation season. Additionally, the LDC methodology is relatively easy to use and cost-effective. The weaknesses of the LDC method are that nonpoint source allocations cannot be assigned to specific sources, and specific source reductions are not quantified. Overall, IEPA believes and EPA concurs that the strengths outweigh the weaknesses for the LDC method.

Implementing the results shown by the LDC requires watershed managers to understand the sources contributing to the water quality impairment and which Best Management Practices (BMPs) may be the most effective for reducing pollutant loads based on flow magnitudes. Different sources will contribute pollutant loads under varying flow conditions. For example, if exceedances are significant during high flow events this would suggest storm events are the cause and implementation efforts can target BMPs that will reduce stormwater runoff and consequently pollutant loading into surface waters. This allows for a more efficient implementation effort.

The TMDLs for the DRSC were calculated as appropriate. The regulated permittees discharging fecal coliform and chloride have allocations determined for them (Table 5-29 of this Decision Document). The load allocations were calculated after the determination of the Margin of Safety. Other load allocations (ex. non-regulated stormwater runoff, wildlife inputs, etc.) were not divided amongst individual nonpoint contributors. Instead, load allocations were combined into a generalized loading.

The LDC for fecal coliform shows exceedences under all flow conditions, and in similar magnitudes, indicating a variety of sources are contributing to the impairment. The LDC for chloride has only four exceedences. These exceedences occurred under mid- to lower-flow conditions.

Tables 5-29 of this Decision Document calculates five points (the midpoints of the designated flow regime) on the loading capacity curves. However, it should be understood that the components of the TMDL equation could be illustrated for any point on the entire loading capacity curve. The load duration curve method can be used to display collected pollutant monitoring data and allows for the estimation of load reductions necessary for attainment of the appropriate water quality standards. Using this method, daily loads were developed based upon the flow in the water body. Loading capacities were determined for the segment for multiple flow regimes. This allows the TMDLs to be represented by an allowable daily load across all flow conditions. Although there are numeric loads for each flow regime, the LDC is what is being approved for these TMDLs.

<u>DO-demanding substances (Segment GB-16)</u>: To develop the TMDL for low DO for Segment GB-16, IEPA used the QUAL2K model (Section 6.2 and Appendices E1-E3 of the TMDL). QUAL2K is a steady state, one-dimensional model that can simulate DO concentrations on an hourly time step (Section 1 of Appendix E1 of the TMDL). Typically, daily data are simulated during critical conditions (e.g., low flow and warm temperatures) and iterated over multiple repeated days to achieve convergence. QUAL2K represents streams as a series of segments, each of which has approximately constant characteristics (e.g., slope, shading, bottom width). Each segment is further divided into a series of equally spaced model computational elements, which are assumed fully mixed. Factors that affect in-stream temperature and DO concentrations are represented in QUAL2K, including solar inputs, stream shading, air temperature, oxidation of suspended and dissolved organic matter. The relative magnitude of these factors can be determined through model application, and scenarios can be developed to evaluate if management actions can improve in-stream conditions.

The results of the QUAL2K modeling show that several factors are contributing to the DO impairment. Segment GB-16 receives flow from three WWTFs, which contribute various substances that consume oxygen. In-stream processes also were found to negatively impact DO levels in the segment. The QUAL2K model was used to investigate several scenarios to meet the WQS (Section 4.2 of Appendix E1 of the TMDL). Two scenarios were determined to attain the DO standard in Segment GB-16:

Scenario 2	Scenario 3
• SOD reduced to 2.04 g/m ² /d	• SOD reduced to 2.04 g/m ² /d
 Point source minimum DO increased to 	Point source minimum DO increased to
6.5 mg/L	6.5 mg/L
 Bolingbrook and Plainfield WWTPs 	 Bolingbrook and Plainfield WWTPs
CBOD decreased to 10 mg/L	CBOD decreased to 10 mg/L
 Headwater total phosphorus decreased to 1 mg/L 	 Headwater total phosphorus decreased to 1 mg/L
 Naperville WWTF CBOD reduced to 7.5 mg/L 	 Naperville WWTF CBOD remains the same
• SOD coverage reduced to 7.5%	• SOD coverage reduced to 5.0%

Table 33:	DO-substance	Scenarios	for Segment	GB-16
	The Concernence			

SOD = Sediment Oxygen Demand

The difference between the two scenarios are noted in italics in Table 33. Results of the modeling determined that SOD was a significant component of low DO in the segment. To reduce SOD in the system, IEPA determined that the total phosphorus coming from upstream sources need to be reduced, as well as reducing pollutants from the three WWTFs (Section 4.2 of Appendix E1 of the TMDL). Controlling these various loads will reduce the intensity of SOD as well as the areal extent of the stream with elevated levels of SOD. Table 30 of this Decision Document summarizes the two sets of allocations for Segment GB-16. For the purposes of this TMDL approval, EPA is approving the allocations for Scenario 2, which are more conservative regarding allocations. However, the EPA notes that IEPA will pursue implementing Scenario 3 through the NPDES permit process. EPA has determined it is reasonable to expect either scenario to attain WQS if implemented appropriately.

<u>DO-demanding substances (GBK-14 and GBKA)</u>: Similar to the process for Segment GB-16, IEPA used QUAL2K to develop the TMDLs for Segments GBK-14 and GBKA (Appendices E2 and E3 of the TMDL). However, the cause of the low DO differs for these two segments. These segments are small headwater streams with no WWTF inputs; IEPA determined the critical condition for low DO was summer very low flow, with no stormwater inputs (Section 6.2 of the TDML). Analysis of the data and modeling results by IEPA showed that the source of the low DO is a more diffuse set of DO-demanding substances than for Segment GB-16. The analysis showed that DO decreases are due to high SOD levels in the streambed, low reaeration rates, and low flow. Typically, low reaeration rates and low flow are not pollutants under the Clean Water Act, and therefore would not require a TMDL. SOD can be a pollutant, but IEPA determined that just controlling SOD alone was not sufficient to attain the WQS.

To address the DO impairment, IEPA used QUAL2K to determine the DO deficit, the measure of the difference between the DO saturation and the DO criterion. By using the QUAL2K model, IEPA was able to calculate the overall DO impacts of various pollutants (i.e., total phosphorus, nitrogen, SOD, CBOD, etc.) as well as stream characteristics (i.e., flow, depth, reaeration rate, etc.) and calculate the overall DO-demanding substances affecting the streams (Appendices E2 and E3 of the TMDL).

Tables 31 and 32 of this Decision Document summarize the TMDLs addressing low DO for these two segments. IEPA noted that in addition to reducing pollutant loads into the waterbodies, changes to the waterbody characteristics (increasing reaeration and flow) in the waterbodies will be needed to attain WQS.

EPA finds that the TMDL document submitted by IEPA satisfies all requirements concerning this third element.

4. Load Allocations (LAs)

EPA regulations require that a TMDL include LAs, which identify the portion of the loading capacity attributed to existing and future nonpoint sources and to natural background. Load allocations may range from reasonably accurate estimates to gross allotments (40 C.F.R. §130.2(g)). Where possible, load allocations should be described separately for natural background and nonpoint sources.

Comment:

<u>Fecal coliform</u>: The LAs for fecal coliform are found in Tables 5-28 of this Decision Document. IEPA identified several nonpoint sources of bacteria in the watersheds, such as agricultural runoff, failing septics, and wildlife. IEPA did not further quantify the LA for bacteria.

<u>Chloride</u>: The LAs for chloride are found in Table 29 of this Decision Document. IEPA identified winter de-icing activities as the likely source of chloride. IEPA did not further quantify the LA for chloride.

<u>DO-demanding substances</u>: The LAs for DO-demanding substances are found in Tables 30-32 of this Decision Document. Several nonpoint sources of DO-demanding substances were identified by IEPA, including SOD and agricultural runoff. IEPA did not further quantify the LAs, but did note several implementation targets that are needed to address nonpoint source reductions of DO-demanding substances in the TMDL.

EPA finds that the TMDL document submitted by IEPA satisfies all requirements concerning this fourth element.

5. Wasteload Allocations (WLAs)

EPA regulations require that a TMDL include WLAs, which identify the portion of the loading capacity allocated to individual existing and future point source(s) (40 C.F.R. §130.2(h), 40 C.F.R. §130.2(i)). In some cases, WLAs may cover more than one discharger, e.g., if the source is contained within a general permit.

The individual WLAs may take the form of uniform percentage reductions or individual mass based limitations for dischargers where it can be shown that this solution meets WQSs and does not result in localized impairments. These individual WLAs may be adjusted during the NPDES permitting process. If the WLAs are adjusted, the individual effluent limits for each permit issued to a discharger on the impaired water must be consistent with the assumptions and requirements of the adjusted WLAs in the TMDL. If the WLAs are not adjusted, effluent limits contained in the permit must be consistent with the individual WLAs specified in the TMDL. If a draft permit provides for a higher load for a discharger than the corresponding individual WLA in the TMDL, the State/Tribe must demonstrate that the total WLA in the TMDL will be achieved through reductions in the remaining individual WLAs and that localized impairments will not result. All permittees should be notified of any deviations from the initial individual WLAs contained in the TMDL. EPA does not require the establishment of a new TMDL to reflect these revised allocations as long as the total WLA, as expressed in the TMDL, remains the same or decreases, and there is no reallocation between the total WLA and the total LA.

Comment:

<u>Fecal coliform</u>: IEPA determined loads for fecal coliform for the dischargers in the DRSC watersheds (Table 34 of this Decision Document; Appendix F of the TMDL). The WLAs are based upon two flow conditions; IEPA used the design average flow (DAF) of the facilities for the lower streamflow regimes (10%-100%) and the design maximum flow (DMF) of the facilities for the high streamflow regime (0%-10%). The appropriate flow was multiplied by the WQS of 200 cfu/100 mL geometric mean and the 400 SSM for the facilities noted in Table 34 of this Decision Document (Section 6.3.1 of the TMDL)

IEPA identified several CSO dischargers in the watershed. For the fecal coliform TMDLs, IEPA reviewed the discharge records from 2013-2015 for CSO events for each of the CSO systems. IEPA determined the maximum discharge event for that time period, and multiplied that flow by the WQS (the 200 counts/100 mL geometric mean and the 400 counts/100 mL SSM) (Section 6.3.1 of the TMDL). Several CSO systems are part of the Metropolitan Water Reclamation District (MWRD) of Greater Chicago Tunnel and Reservoir Plan (TARP). These systems

convey stormwater into a series of tunnels and reservoirs for storage before pumping the water out, treating it, and discharging to a waterbody. IEPA reviewed the data submitted by MWRD to determine the estimated maximum volume for discharge, and multiplied the flow by the appropriate WQS (Section 6.3.1 and Appendix F of the TMDL).

For MS4s, IEPA determined the land area within each segment watershed that was considered "developed" and assigned that portion of the runoff load to MS4s (Section 6.3.1 of the TMDL). Loads were determined as an aggregate load; loads were not determined for each individual MS4 permittee. Appendix J of the TMDL contains a list of all MS4 permittees in the two watersheds.

For several of the impaired waterbodies, the DAF exceeded the monitored instream flow. For these flow regimes, IEPA noted that the WLAs and LAs are a formula as noted in the TMDL tables in this Decision Document. The WLAs and LAs are expressed as the facility flow times the appropriate WQS (i.e., 500 mg/L for chloride). This applies to both fecal coliform and chloride.

<u>Chloride</u>: IEPA identified four individually permitted dischargers of chloride (Table 35 of this Decision Document) in Segment GB-11. Similar to the bacteria TMDLs, IEPA utilized the DMF for the high flow regime and the DAF for the remaining flow regimes (Section 6.3.1 of the TMDL). The DMF or the DAF was multiplied by the chloride WQS of 500 mg/L to determine the WLA for each facility. For MS4s, a similar process as described above for bacteria was used, where the developed land proportion was multiplied by the WQS (Table 35 of the TMDL). However, IEPA did separate out a WLA for ILDOT, based upon the road mileage in the subwatershed and multiplying that value by the chloride WQS.

<u>DO-demanding substances</u>: IEPA identified three individual point sources discharging DOdemanding substances in Segment GB-16 (Section 7.2.2 of the TMDL). As discussed in Section 3 of this Decision Document, a significant modeling effort was performed to determine the causes and impacts of various DO-demanding substances on the DO levels in the waterbody segment. IEPA determined that two scenarios could result in attaining the DO WQS. Table 30 of this Decision Document (Table 34 of the TMDL) contains the WLAs for the three facilities. WLAs were determined for CBOD, total phosphorus, and total ammonia.

The EPA is approving the WLAs in Scenario 2 (discussed above in Section 3 of the Decision Document) at this time, but notes that the allocations in Scenario 3 are consistent with the TMDL loading capacity, assuming that the additional NPDES permit conditions and implementation targets are met. The EPA is clarifying that it is <u>not</u> approving effluent limits as noted in Table 30 of this Decision Document (Table 34 of the TMDL), or permit conditions as contained in Appendix G of the TMDL. Permit conditions and issues will need to be pursued through the NPDES permit process. Both scenarios include a WLA = 0 for MS4 discharges. IEPA explained that the modeling effort for all three DO-impaired segments focused on the critical conditions when the DO criteria were exceeded, which are during low-flow high temperature summer conditions. IEPA noted that under higher in-stream flows, MS4 discharge at current levels should have no impact on DO levels in the waterbody (email from Abel Haile, IEPA dated 09/05/2019).

EPA finds that the TMDL document submitted by IEPA satisfies all requirements concerning this fifth element.

6. Margin of Safety (MOS)

The statute and regulations require that a TMDL include a margin of safety (MOS) to account for any lack of knowledge concerning the relationship between load and wasteload allocations and water quality (CWA $\S303(d)(1)(C)$, 40 C.F.R. \$130.7(c)(1)). EPA's 1991 TMDL Guidance explains that the MOS may be implicit, i.e., incorporated into the TMDL through conservative assumptions in the analysis, or explicit, i.e., expressed in the TMDL as loadings set aside for the MOS. If the MOS is implicit, the conservative assumptions in the analysis that account for the MOS must be described. If the MOS is explicit, the loading set aside for the MOS must be identified.

Comment:

<u>Fecal coliform</u>: The DRSC bacteria TMDLs incorporate an explicit MOS of 10% of the total loading capacity (Section 6.3.2 of the TMDL and Tables 5-28 of this Decision Document). An additional conservative assumption is that IEPA did not use a rate of decay, or die-off rate of pathogen species, in the TMDL calculations or in the creation of the load duration curve for fecal coliform. Bacteria have a limited capability of surviving outside their hosts, and normally a rate of decay would be incorporated. IEPA determined that it was more conservative to use the WQS (200/400 counts/100 mL) and not to apply a rate of decay, which could result in a discharge limit greater than the WQS.

As stated in *EPA's Protocol for Developing Pathogen TMDLs* (EPA 841-R-00-002), many different factors affect the survival of pathogens, including the physical condition of the water. These factors include, but are not limited to sunlight, temperature, salinity, and nutrient deficiencies. These factors vary depending on the environmental condition/circumstances of the water, and therefore it would be difficult to assert that the rate of decay caused by any given combination of these environmental variables was sufficient to meet the WQS of 200 cfu/100 mL. Thus, it is more conservative to apply the State's WQS as the MOS, because this standard must be met at all times under all environmental conditions.

<u>Chloride</u>: The chloride TMDL for Segment GB-11 incorporates an explicit MOS of 10% of the total loading capacity. The MOS reserved 10% of the loading capacity and allocated the remaining loads to point and nonpoint sources (Table 29 of this Decision Document). The use of the LDC approach minimized variability associated with the development of the chloride TMDL because the calculation of the loading capacity was a function of flow multiplied by the target value. The MOS was set at 10% to account for uncertainty due to field sampling error and assumptions made during the TMDL development process.

<u>DO-demanding substances</u>: The TMDLs addressing the DO impairments in the DRSC watersheds incorporate an implicit MOS regarding the loading capacity. IEPA used a DO target that is 10% higher than the applicable criterion. For Segment GB-16, the WQS is a minimum of 5.0 mg/L. In the QUAL2K model, IEPA developed the TMDL to meet a target of 5.5 mg/L. For Segments GBK-14 and GBKA, the WQS is the minimum of >4.0 mg/L. The target for both

TMDLs is a DO minimum of >4.4 mg/L. The MOS was set to account for uncertainty due to field sampling error and assumptions made during the TMDL development process.

EPA finds that the TMDL document submitted by IEPA has an appropriate MOS satisfying all requirements concerning this sixth element.

7. Seasonal Variation

The statute and regulations require that a TMDL be established with consideration of seasonal variations. The TMDL must describe the method chosen for including seasonal variations. (CWA 303(d)(1)(C), 40 C.F.R. 130.7(c)(1)).

Comment:

The LDC process accounts for seasonal variation by utilizing streamflows over a wide range. The LDC graphs can be used to determine under which conditions exceedences are occurring, and any seasonal component (i.e., spring melt).

Bacterial loads vary by season, typically reaching higher values in the dry summer months when low flows and warm water contribute to increased bacteria abundance, and reaching relatively lower values in colder months when bacterial growth rates attenuate. Bacterial WQS need to be met between May 1st to October 31st, regardless of the flow condition. The development of the LDC utilized flow measurements from local flow gages. These flow measurements were collected over a variety of flow conditions observed during the recreation season. The LDC developed from these flow records represents a range of flow conditions within the impaired watersheds and thereby accounted for seasonal variability over the recreation season.

For chloride, the development of the LDC utilized flow measurements from local flow gages. These flow measurements were collected over a variety of flow conditions observed during the year. The LDC developed from these flow records represents a range of flow conditions within the impaired watersheds and thereby accounted for seasonal variability over the year.

For the DO-demanding substances, analysis of the DO data indicated that DO was a problem during the late summer, when flows and reaeration are the lowest, and the impacts of the pollutants the greatest (Appendices E1-E3 of the TMDL). IEPA focused the modeling effort in this time period to determine the allocations necessary to attain WQS under the most conservative conditions.

EPA finds that the TMDL document submitted by IEPA satisfies all requirements concerning this seventh element.

8. Reasonable Assurances

When a TMDL is developed for waters impaired by point sources only, the issuance of a National Pollutant Discharge Elimination System (NPDES) permit(s) provides the reasonable assurance that the wasteload allocations contained in the TMDL will be achieved. This is because 40 C.F.R. 122.44(d)(1)(vii)(B) requires that effluent limits in permits be consistent with

"the assumptions and requirements of any available wasteload allocation" in an approved TMDL.

When a TMDL is developed for waters impaired by both point and nonpoint sources, and the WLA is based on an assumption that nonpoint source load reductions will occur, EPA's 1991 TMDL Guidance states that the TMDL should provide reasonable assurances that nonpoint source control measures will achieve expected load reductions in order for the TMDL to be approvable. This information is necessary for EPA to determine that the TMDL, including the load and wasteload allocations, has been established at a level necessary to implement water quality standards.

EPA's August 1997 TMDL Guidance also directs Regions to work with States to achieve TMDL load allocations in waters impaired only by nonpoint sources. However, EPA cannot disapprove a TMDL for nonpoint source-only impaired waters, which do not have a demonstration of reasonable assurance that LAs will be achieved, because such a showing is not required by current regulations.

Comment:

Section 8 of the TMDL discusses reasonable assurance for the DRSC watershed TMDLs. IEPA provided information on controls of fecal coliform, chloride, and DO-demanding substances that will be targeted in the watershed.

Point Sources:

Reasonable assurance that the WLAs will be implemented are through the NPDES program. IEPA listed numerous WWTPs that discharge the pollutants of concern in the DRSC watershed. WLAs have been determined for all three pollutants, and individual WLAs calculated for each point source discharger. Stormwater was identified as a source of the three pollutants, and IEPA has determined aggregate WLAs for each pollutant by subwatershed. As discussed in Section 5 of this Decision Document, IEPA developed two scenarios to address the low-DO in Segment GB-16. These scenarios will require reductions in pollutant loads for the three WWTF dischargers on the segment.

Appendix G of the TMDL contains the NPDES Permit Special Condition either contained or to be contained in the NPDES permits for the permittees listed in Table 34-35 of this Decision Document. These conditions require the permittee to work with the DRSCW to determine the most effective means to address the chloride and low DO impairments in the DRSC watersheds. The Special Conditions include various projects to address other causes of the DO impairment, such as dam removal, waterbody restoration, and additional modeling efforts. Completion dates are included, and annual progress reports are required. The latest progress report is available at http://www.dupagerivers.org/wp-content/uploads/2018/04/DRSCW-LDRWC SpecialConditionsReport17-18 03312018.pdf on the DRSCW website.

The Special Conditions also require implementation of a watershed Chloride Reduction Program, and to work with members of the DRSCW to reduce chloride discharge. A Phosphorus Discharge Optimization Plan is also required to be implemented to investigate the potential for

further reductions in phosphorus discharge from the facilities. The Permittees are also required to investigate nonpoint source phosphorus reductions through a Nutrient Implementation Plan.

Nonpoint Sources:

<u>Fecal coliform</u>: Section 8.5 of the TMDL discusses various BMPs that, when implemented, will significantly reduce fecal coliform loadings to attain WQS. For most of these BMPs, IEPA provided watershed analysis on the impacts these BMPs may have on fecal coliform loads. IEPA noted that the usual source of bacteria loading (agricultural runoff), is not present in much of the watershed. For the East Branch DuPage River and Salt Creek, nonpoint source actions will focus on sanitary surveys to identify failing septics. The West Branch DuPage River and Lower DuPage River have some agricultural lands, and therefore some controls will be needed for those sources.

<u>Chloride</u>: To control chloride loads into the Lower DuPage River, IEPA will focus on controlling road salt runoff in the watershed (Section 8.5.3 of the TMDL). To control chloride, IEPA will focus on operator training for both municipal salting operations as well as private contractors.

<u>DO-demanding substances</u>: To control DO-demanding substances in the TMDL watersheds, IEPA developed a STEPL model that calculates pollutant runoff from various land uses (Section 8 of the TMDL). Figures 69 and 71 in the TMDL identify the phosphorus and BOD loading rates from subwatersheds in the Segment GB-16 watershed. This modeling effort will help IEPA identify the critical areas for pollutant loading, and therefore target BMPs more efficiently.

Local efforts:

IEPA also identified numerous watershed projects in the TMD watershed that will reduce pollutant loads. The DRSCW is a local group of stakeholders that have been working in the watersheds for many years. Tables 66 and 67 of the TMDL contain a list of BMP projects planned for the East Branch and West Branch DuPage Rivers, including costs. The Lower DuPage River Watershed Coalition (LDRWC) has also been active in the watershed. Both groups have applied for and received funding to develop implementation actions and activities, perform monitoring, and target the removal of dams in the watershed. These projects will directly reduce pollutant loads in the waterbodies, as well as improve fish passages, habitat and biota within the impaired waters.

Additional TMDLs:

IEPA noted that several previously approved TMDLs in different portions of the watershed continue to be implemented (Table 2 of the TMDL and

https://www2.illinois.gov/epa/topics/water-quality/watershed-

management/tmdls/Pages/reports.aspx#dupeas). Previous TMDLs in the East Branch DuPage River focused on low DO and elevated chloride. TMDLs in the West Branch DuPage River addressed elevated chloride levels. TMDLs in Salt Creek addressed chloride and low DO. These TMDLs are being implemented, and the actions and activities as part of this implementation effort will very likely help reduce pollutants in the DRSC TMDLs (Section 8 of the TMDL).

DuPage River and Salt Creek 2, IL Final Decision Document EPA finds that this criterion has been adequately addressed.

9. Monitoring Plan to Track TMDL Effectiveness

EPA's 1991 document, *Guidance for Water Quality-Based Decisions: The TMDL Process* (EPA 440/4-91-001), recommends a monitoring plan to track the effectiveness of a TMDL, particularly when a TMDL involves both point and nonpoint sources, and the WLA is based on an assumption that nonpoint source load reductions will occur. Such a TMDL should provide assurances that nonpoint source controls will achieve expected load reductions and, such TMDL should include a monitoring plan that describes the additional data to be collected to determine if the load reductions provided for in the TMDL are occurring and leading to attainment of water quality standards.

Comment:

The TMDL contains discussion on future monitoring and milestones (Section 9 and Table 70 of the TMDL). There were several monitoring sites used to gather data for the DRSC TMDLs. IEPA performs intensive basin surveys every 5 years on a rotating basins process. Additional monitoring has been done by the DRSCW and LDRWC who have worked in conjunction with IEPA and NPDES permittees in the watershed to gather a wide variety of data to better document the water quality. Some of the monitoring work is required under the Special Conditions in the NPDES permits (Appendix G of the TMDL).

EPA finds that this criterion has been adequately addressed.

10. Implementation

EPA policy encourages Regions to work in partnership with States/Tribes to achieve nonpoint source load allocations established for 303(d)-listed waters impaired by nonpoint sources. Regions may assist States/Tribes in developing implementation plans that include reasonable assurances that nonpoint source LAs established in TMDLs for waters impaired solely or primarily by nonpoint sources will in fact be achieved. In addition, EPA policy recognizes that other relevant watershed management processes may be used in the TMDL process. EPA is not required to and does not approve TMDL implementation plans.

Comment:

Numerous implementation options are discussed in Section 8 of the TMDL. Many of the options focus on stormwater controls and stream restoration activities.

The potential BMPs are:

- Ordinance development local ordinances can have significant impacts on the design and operation of stormwater controls
- Pet waste education reduction of bacteria and nutrients through implementation of controls on pet waste
- Septic System Inspection improved septic system regulations and point of sale inspections can reduce the potential for failing systems

- Green infrastructure the use of permeable paving, rain gardens, etc. to reduce and control stormwater runoff
- Stream restoration the DRSCW and LDRWC have led efforts to improve streams within the TMDL watersheds
- Dam removal Several dams have been removed or reduced to provide better stream hydrology and fish passage in the watersheds

IEPA also provided data on the potential removal efficiencies for several BMPs in Table 66 of the TMDL. The table also provides information on potential costs for the BMPs.

Significant efforts have been developed in the watershed to address the reduction of chloride in the watershed. The DRSCW and LDRWC have led efforts to develop and host annual workshops for public and private salt spreaders since 2008. The groups have also developed BMPs regarding salt practices in an effort to reduce salt loads throughout the watershed. A variety of best practices information and training materials are available on the DRSCW website (http://www.drscw.org/wp/chlorides-and-winter-management/).

EPA reviews, but does not approve, implementation plans. EPA finds that this criterion has been adequately addressed.

11. Public Participation

EPA policy is that there should be full and meaningful public participation in the TMDL development process. The TMDL regulations require that each State/Tribe must subject calculations to establish TMDLs to public review consistent with its own continuing planning process (40 C.F.R. §130.7(c)(1)(ii)). In guidance, EPA has explained that final TMDLs submitted to EPA for review and approval should describe the State's/Tribe's public participation process, including a summary of significant comments and the State's/Tribe's responses to those comments. When EPA establishes a TMDL, EPA regulations require EPA to publish a notice seeking public comment (40 C.F.R. §130.7(d)(2)).

Provision of inadequate public participation may be a basis for disapproving a TMDL. If EPA determines that a State/Tribe has not provided adequate public participation, EPA may defer its approval action until adequate public participation has been provided for, either by the State/Tribe or by EPA.

Comment:

An initial public meeting was held on January 28, 2009, to describe the watershed plan and TMDL process. An additional stakeholder meeting was held on March 31, 2009. The TMDL process, NPDES Special Conditions, and project status in the watersheds were discussed during meetings of the DRSCW. The meetings were held approximately every 2 months. Numerous stakeholders were present at the meetings (http://www.drscw.org/wp/agendas-and-minutes/).

The public comment period for the draft TMDL opened on April 24, 2019 and closed on May 24, 2019. A public meeting was held on April 24, 2019, in Lombard, Illinois. The public notices

were published in the local newspaper and interested individuals and organizations received copies of the public notice. A hard copy of the TMDL was made available at the Conservation Foundation, DuPage County Stormwater Management Office, the Village of Lombard, and the Village of Plainfield. The draft TMDL was also made available at the website http://www.epa.illinois.gov/public-notices/index. One public comment was received, from the Metropolitan Water Reclamation District of Greater Chicago (Appendix D of the TMDL). The comments corrected the locations of several monitoring stations operated by the District. IEPA revised the TMDL as appropriate based on the comments.

EPA finds that the TMDL document submitted by IEPA satisfies all requirements concerning this eleventh element.

12. Submittal Letter

A submittal letter should be included with the TMDL submittal, and should specify whether the TMDL is being submitted for a *technical review* or *final review and approval*. Each final TMDL submitted to EPA should be accompanied by a submittal letter that explicitly states that the submittal is a final TMDL submitted under Section 303(d) of the Clean Water Act for EPA review and approval. This clearly establishes the State's/Tribe's intent to submit, and EPA's duty to review, the TMDL under the statute. The submittal letter, whether for technical review or final review and approval, should contain such identifying information as the name and location of the waterbody, and the pollutant(s) of concern.

Comment:

On August 6, 2019, EPA received the DRSC watershed TMDLs and a submittal letter from Sanjay Sofat, IEPA to Joan Tanaka, EPA. In the submittal letter, IEPA stated it was submitting the TMDL report for EPA's final approval. The submittal letter included the name and location of the waterbodies and the pollutants of concern.

EPA finds that the TMDL document submitted by IEPA satisfies all requirements concerning this twelfth element.

Conclusion

After a full and complete review, EPA finds that the TMDLs for the DuPage River Salt Creek watersheds satisfy all of the elements of an approvable TMDL. This approval is for 18 TMDLs: 12 for fecal coliform, five for low DO (phosphorus, ammonia, CBOD, and DO-demanding substances) and one for chloride, as noted in Table 1 of this Decision Document.

EPA's approval of this TMDL does not extend to those waters that are within Indian Country, as defined in 18 U.S.C. Section 1151. EPA is taking no action to approve or disapprove TMDLs for those waters at this time. EPA, or eligible Indian Tribes, as appropriate, will retain responsibilities under the CWA Section 303(d) for those waters.

Fecal Coliform TMDLs

Table 34 of this Decision Document contains the individual WLAs summarized in Tables 5-28.

Table 5. Fecal coliform TMDL summary (single sample maximum standard; Du	Page River at GB-
11)	

		Flow Zones				
TMDL Parameter		High Flows	Moist Conditions	Mid-Range Flows	Dry Conditions	Low Flows
		Fecal Coliform Load (billion cfu/day)				
	CSOs °	372	-	-	-	
Wasteload Allocation	NPDES-permitted facilities	4,825	2,134	2,134	b	b
	MS4 ^d	5,641	1,931	339	b	b
Load Allocation	6	769	263	46	b	b
MOS		1,290	481	280	183	126
Loading Capacit	ty	12,897	4,809	2,799	1,830	1,260
Existing Load		34,398	12,109	5,271	1,481	1,764
Load Reduction a		63%	60%	47%	0%	29%

a. TMDL reduction is based on the observed 90th percentile load in each flow regime.

b. The permitted wastewater treatment facility design flows exceed the long-term monitored stream flow in the dry and low flow zones. NPDES-permitted facilities can discharge under these flow conditions if meeting permit conditions. To account for these unique situations only, the WLAs and LA are expressed as an equation rather than an absolute number. Wasteload Allocation or Load Allocation = (flow contribution from a given source) x (400 counts per 100 mL). The allowable concentration is based on water quality standards.

c. CSO events are assumed to occur no more than 4 times a year

d. the MS4 WLA is categorical, see section 6.3.1 for description

Table 6. Fecal coliform TMDL summary (geomean standard; DuPage River at GB-11)

		Flow Zones				
TMDL Parameter		High Flows	Moist Conditions	Mid-Range Flows	Dry Conditions	Low Flows
		Fecal Coliform Load (billion cfu/day)				
	CSOs °	186	-		-	-
Wasteload Allocation	NPDES-permitted facilities	2,415	1,065	1,065	b	b
2	MS4 ^d	2,819	967	172	b	b
Load Allocation		384	132	23	b	b
MOS		645	240	140	92	63
Loading Capacity		6,449	2,404	1,400	915	630
Existing Load		34,398	12,109	5,271	1,481	1,764
Load Reduction ^a		Not calculated				

a. Insufficient data to calculate reduction based on the geomean standard.

b. The permitted wastewater treatment facility design flows exceed the long-term monitored stream flow in the dry and low flow zones. NPDES-permitted facilities can discharge under these flow conditions if meeting permit conditions. To account for these unique situations only, the WLAs and LA are expressed as an equation rather than an absolute number: Wasteload Allocation or Load Allocation = (flow contribution from a given source) x (200 counts per 100 mL). The allowable concentration is based on water quality standards.

c. CSO events are assumed to occur no more than 4 times per year.

d. The MS4 WLA is categorical, see section 6.3.1 for description.

DuPage River and Salt Creek 2, IL Final Decision Document

		Flow Zones				
TMDL Parameter		High Flows	Moist Conditions	Mid-Range Flows	Dry Conditions	Low Flows
		Fecal Coliform Load (billion cfu/day)				
	CSOs °	372		-	-	-
Wasteload Allocation	NPDES-permitted facilities	4,707	2,086	b	b	b

Table 7. Fecal coliform TMDL summary (single sample maximum standard; DuPage River at GB-16)

a. TMDL reduction is based on the observed 90th percentile load in each flow regime.

b. The permitted wastewater treatment facility design flows exceed the long-term monitored stream flow in the dry and low flow zones. NPDES-permitted facilities can discharge under these flow conditions if meeting permit conditions. To account for these unique situations only, the WLAs and LA are expressed as an equation rather than an absolute number: Wasteload Allocation or Load Allocation = (flow contribution from a given source) x (400 counts per 100 mL). The allowable concentration is based on water quality standards.

c. CSO events are assumed to occur no more than 4 times per year.

d. The MS4 WLA is categorical, see section 6.3.1 for description

a. CSO events are assumed to occur no more than 4 times per year.

b. Permitted CSO loads are estimated to be approximately 5,940 billion cfu/event. Permitted CSO facilities can

discharge under high flow conditions if meeting permit conditions and long-term control plans.

c. The permitted wastewater treatment facility design flows exceed the long-term monitored stream flow in the dry and low flow zones. NPDES-permitted facilities can discharge under these flow conditions if meeting permit conditions. To account for these unique situations only, the WLAs and LA are expressed as an equation rather than an absolute number: Wasteload Allocation or Load Allocation = (flow contribution from a given source) x (200 counts per 100 mL). The allowable concentration is based on water quality standards.

d. The MS4 WLA is categorical, see section 6.3.1 for description.

e. Insufficient data to calculate reduction based on the geomean standard.

Table 27. Fecal coliform TMDL summary (single sample maxi	mum standard; Addison Creek at
GLA-02)	

- TMDL Parameter		Flow Zones				
		High Flows	Moist Conditions	Mid-Range Flows	Dry Conditions	Low Flows
			Fecal Colif	orm Load (billi	on cfu/day)	
	CSO: IL0020853 (MWRDGC STICKNEY WRP CSOS – 150) ^a	b	-	-		-

Acknowledgements

AECOM Environment developed portions of Sections 1-6 while under contract with Illinois EPA between 2008 and 2012 (see Appendix A).

The DuPage River Salt Creek Work Group and staff from the Conservation Foundation were integral in developing Section 8 to reflect local priorities in addition to providing support throughout the remainder of the project including gathering additional monitoring data (dissolved oxygen, pH, and other parameters) on selected streams to support the TMDL development process.

Executive Summary

The Clean Water Act and U.S. Environmental Protection Agency (EPA) regulations require that Total Maximum Daily Loads (TMDLs) be developed for waters that do not support their designated uses. In simple terms, a TMDL is a plan to attain and maintain water quality standards in waters that are not currently meeting them. The State of Illinois uses a three-stage approach to develop TMDLs for a watershed:

- **Stage 1** Watershed characterization, historical dataset evaluation, data analysis, methodology selection, data gap identification
- Stage 2 Data collection to fill in data gaps, if necessary
- Stage 3 Model calibration, TMDL scenarios, and implementation plan

This TMDL study addresses the approximately 520 square mile DuPage River and Salt Creek watersheds located in northeastern Illinois. Fifteen stream segments within the watershed have identified impairments and have been placed on the State of Illinois §303(d) list. TMDL allocations have been set for fecal coliform, chloride and dissolved oxygen. Additional impairments in the watershed include nutrients and sediment. TMDLs are not provided for these impairments and needed reductions to meet water quality standards are unknown, however, implementation strategies to address nutrient and sediment impairments are provided in the implementation section of this report.

The sources of pollutants in the watershed include NPDES permitted facilities such as wastewater treatment facilities, combined sewer overflows, and regulated stormwater. In addition, sources of nonpoint pollution are largely the result of stormwater runoff in urban and rural areas. Stormwater, while not an actual source of pollutants itself, acts as an important delivery mechanism of multiple sources of each pollutant (e.g., pet waste, wildlife waste, salt application). In urban areas, non-permitted cross connections between sanitary sewers and storm sewers can also occur. Sources of pollutants in rural areas are primarily related to nutrient and sediment loading as a result of crop production in the Lower DuPage River watershed.

A TMDL identifies the total allowable load that a waterbody can assimilate (the loading capacity) and still meet water quality standards or targets. The loading capacity for fecal coliform or chloride stream impairments is determined using a load duration curve framework. The loading capacity for low dissolved oxygen impairments is derived using the receiving water model Qual2K. TMDLs and needed load reductions are presented in Section 7. The TMDL, or loading capacity, is distributed among point sources as wasteload allocations and nonpoint and background sources as load allocations. A margin of safety is provided to account for uncertainty. The required pollutant reductions vary between zero and 96%, depending on the waterbody, flow regime, and pollutant.

An implementation plan is provided in Section 8 which includes potential implementation activities to address the various pollutant sources in the watershed. The implementation plan covers only the DuPage River watershed portion of the TMDL. An implementation planning effort is underway for the Salt Creek watershed by the Chicago Metropolitan Agency for Planning, DuPage County Stormwater Management, and the DuPage River Salt Creek Workgroup that will address both the impaired waters in the Salt Creek watershed as well as other water quality concerns. The implementation plan, when combined with the TMDLs, is expected to meet U.S. EPA's Nine Elements for Clean Water Act section 319 funding requirements and includes an analysis of critical areas, extent of needed implementation, schedule, milestones, partners, and estimated costs.

1.0 Introduction

This final Stage 3 Total Maximum Daily Load (TMDL) report is presented by Illinois Environmental Protection Agency (Illinois EPA) as part of the state's Clean Water Act (CWA) Section 303(d) compliance obligations. The purpose of the project is to develop TMDLs for fifteen designated waterbodies in the DuPage River and Salt Creek watersheds in northeastern Illinois.

Section 303(d) of the CWA and U.S. Environmental Protection Agency's (USEPA) Water Quality Planning Regulations (40 CFR Part 130) require states to develop TMDLs for impaired waterbodies that are not meeting designated uses or water quality standards. A TMDL is a calculation of the maximum amount of pollutants that a waterbody can receive and still meet the water quality standards and targets necessary to protect the designated beneficial use (or uses) for that waterbody. The TMDL process establishes the allowable loadings of pollutants for a waterbody based on the relationship between pollutant sources and water quality conditions, so that states and local communities can establish water quality based controls to reduce pollutants from both point and nonpoint sources and restore and maintain the quality of their water resources. In addition to TMDL development, Load Reduction Strategies (LRS) may be included to address additional pollutants in the watershed that do not have water quality standards, namely nutrients and sediment in streams. In the case of the DuPage River and Salt Creek Work Group and the Lower DuPage River Watershed Coalition and their high level of activity addressing water quality and impairments in the watershed.

United States policies and regulations, such as the CWA, were created and are implemented to help maintain the quality of our water resources in the United States. The USEPA, via the CWA, charged each state with developing water quality standards (WQS). These WQS are laws or regulations that states authorize to protect and/or enhance water quality, to ensure that a waterbody's designated use (or uses) is (are) not compromised by poor water quality and to protect public health and welfare. In general, WQS consist of three elements:

- The designated beneficial use (e.g., recreation, protection of aquatic life, aesthetic quality and public and food processing water supply) of a waterbody or segment of a waterbody
- The water quality criteria necessary to support the designated beneficial use of a waterbody or segment of a waterbody
- An anti-degradation policy, so that water quality improvements are conserved, maintained and protected

The Illinois Pollution Control Board (IPCB) established its WQS and includes it in Title 35: Environmental Protection, Subtitle C: Water Pollution, Chapter 1: Pollution Control Board, Part 302: Water Quality Standards. Every two years the Illinois EPA submits the Illinois Integrated Water Quality Report and Section 303(d) List. This report documents surface and groundwater conditions throughout the state and identifies impaired waterbodies, grouped by watershed, and identifies suspected sources of impairment.

The TMDL process establishes the allowable loading of pollutants or other quantifiable parameters for a water body based on the relationship between pollution sources and instream conditions. This allowable loading represents the maximum quantity of the pollutant that the waterbody can receive without exceeding water quality standards. The TMDL also takes into account a margin of safety, which reflects scientific uncertainty, as well as the effects of seasonal variation. By following the TMDL process, States can establish water qualitybased controls to reduce pollution from both point and nonpoint sources, and restore and maintain the quality of their water resources. The Illinois EPA will be working with stakeholders to implement the necessary controls to improve water quality in the impaired waterbodies and meet water quality standards.

Illinois EPA uses a three-stage approach to develop TMDLs for a watershed:

- Stage 1 Watershed characterization, historical dataset evaluation, data analysis, methodology selection, data gap identification (see Appendix A)
- Stage 2 Data collection to fill in data gaps, if necessary
- Stage 3 Model calibration, TMDL scenarios, and implementation plans

The purpose of Stage 1 (Appendix A) is to characterize the watershed background; verify impairments in the listed waterbody by comparing observed data with water quality standards or appropriate targets; evaluate spatial and temporal water quality variation; provide a preliminary assessment of sources contributing to impairments; and describe potential TMDL development approaches. If available water quality data collected for the watershed are deemed sufficient by Illinois EPA, Stage 2 may be omitted and Stage 3 will be completed. If sufficient water quality data or supporting information are lacking for an impaired waterbody, then Stage 2 is required and field samplings will be conducted in order to obtain necessary data to complete Stage 3. For the DuPage River/Salt Creek Watershed, Stage 2 sampling was conducted for sediment oxygen demand (SOD) in the West Branch and mainstem of the DuPage River (Appendix B). In addition, additional data collected was conducted on select segments to further characterize dissolved oxygen conditions. These data, while collected as part of Stage 2, are incorporated throughout the document where applicable. Stage 3 includes model development, allocations and reductions needed for waterbody improvement, and implementation actions for local stakeholders.

1.1 Definition of a Total Maximum Daily Load (TMDL)

According to the 40 CFR Part 130.2, the TMDL (the maximum load a waterbody can receive without exceeding water quality standards or result in non-attainment of a designated use) for a waterbody is equal to the sum of the individual loads from point sources (i.e., waste load allocations or WLAs) and load allocations (LAs) from nonpoint sources (including natural background conditions). Section 303(d) of the CWA also states that the TMDL must be established at a level necessary to achieve the applicable water quality standards with seasonal variations and a margin of safety (MOS) that takes into account any lack of knowledge concerning the relationship between effluent limitations and water quality. A reserve capacity (RC) can be included to account for future growth. In equation form, a TMDL may be expressed as follows:

TMDL = WLA + LA + MOS + RC

where:

1010.	
WLA =	Waste Load Allocation (i.e., loadings from point sources)
LA =	Load Allocation (i.e., loadings from nonpoint sources including natural background)
MOS =	Margin of Safety
RC=	Reserve Capacity

The MOS accounts for the lack of knowledge or uncertainty concerning the true relationship between loading and attainment of water quality standards. This uncertainty is often a product of data gaps, either temporally or spatially, in the measurement of water quality. The MOS should be proportional to the anticipated level of uncertainty; the higher the uncertainty, the greater the MOS. The MOS can be either explicit or implicit. If an explicit MOS is used, a portion of the total allowable loading is allocated to the MOS. If the MOS is implicit, a specific value is not assigned to the MOS, but is already factored in during the TMDL development process. Use of an implicit MOS is appropriate when assumptions used to develop the TMDL are believed to be so conservative that they sufficiently account for the MOS. An RC is set aside to accommodate future growth in the watershed; this allocation can then be assigned to the appropriate permitted facility as needed. No specific reserve capacity is set aside at this time. TMDLs also shall take into account the seasonal variability of pollutant loading and hydrology to ensure water quality standards are met in all seasons and during all hydrologic conditions.

1.2 Targeted Waterbodies for TMDL Development

Several waters within the DuPage River/Salt Creek watershed have been placed on the State of Illinois §303(d) list (Table 1, Figure 1, and Figure 2) and require development of TMDLs. Appendix C includes photographs of several streams in the watershed.

Each waterbody has one or more designated uses, which may include aquatic life, aesthetic quality, indigenous aquatic life (for specific Chicago-area waterbodies), primary contact (swimming), secondary contact (recreation), public and food processing water supply, and fish consumption. The degree of support (attainment) of a designated use in a waterbody (or segment) is assessed as Fully Supporting (good), Not Supporting (fair), or Not Supporting (poor). Waters in which at least one applicable use is not fully supported is designated as "impaired." Potential causes and sources of impairment are also identified for these waters. The 303(d) List is prioritized on a watershed basis based on the requirements of 40 CFR Part 130.7(b)(4).

Fifteen river segments are identified as impaired in the DuPage River/Salt Creek Watershed on the 2014 and 2016 draft 303(d) lists. Water quality assessments are based on biological, physicochemical, physical habitat, and toxicity data. The causes of impairment include pollutants such as fecal coliform, nickel, copper and chloride. Other causes of impairment include pH, low dissolved oxygen, total phosphorus, sedimentation/siltation, and total suspended solids. For impairments caused by low dissolved oxygen, the dissolved oxygen parameter itself is not calculated as a TMDL but is addressed by developing a TMDL for the parameters determined to be the primary cause of the dissolved oxygen impairment.

2.0 Public Participation and Involvement

The Illinois EPA is committed to keeping the watershed stakeholders and general public informed and involved throughout the TMDL process. Success for any TMDL implementation plan relies on a knowledgeable public to assist in follow-through required for attainment of water uses within their watershed. It is important to engage the local citizens as early in the process as possible by providing opportunities to learn and process information. This ensures that concerns and issues are identified at an early stage, so that they can be addressed and facilitate maximum cooperation in the implementation of the recommended courses of actions identified in the TMDL process. All stakeholders should have access to enough information to allay concerns, gain confidence in the TMDL process and understand the purpose and the regulatory authority or other responsible party that will implement recommendations.

General information regarding the process of TMDL development in Illinois can be found at <u>https://www2.illinois.gov/epa/topics/water-quality/watershed-management/tmdls/Pages/default.aspx</u>. The public notice/meeting and information about the draft stage 3 TMDL report was available at the Agency's Public Notices webpage at <u>https://www2.illinois.gov/epa/public-notices/Pages/default.aspx</u>.

Background information regarding watersheds, watershed management, best management practices and the CWA can be found on the EPA's water website at <u>http://www.epa.gov/watertrain/</u>.

For other reports and studies concerning the DuPage River and Salt Creek watershed, please visit the DuPage River Salt Creek Workgroup (<u>http://www.drscw.org/</u>) and the Lower DuPage River Watershed Coalition (<u>http://www.dupagerivers.org/</u>). The websites contains reports, data and additional links related to this watershed. In addition, DuPage County has conducted several watershed planning and implementation projects (http://www.dupageco.org/swm/) and Chicago Metropolitan Area Planning is currently conducting watershed planning activities in the Salt Creek watershed (<u>http://www.cmap.illinois.gov/programs-and-resources/lta/lower-salt-creek</u>).

2.1 Public Input

The Illinois EPA regularly met with the DuPage River Salt Creek Workgroup and Lower DuPage River Watershed Coalition to keep them informed on the TMDL progress.

A stage one public meeting was held in Elmhurst on January 28, 2009 (6:00 pm). The Illinois EPA provided public notices for all meetings by placing an ad in the local newspapers in the watershed; the Chicago Daily Herald, The Will-South DuPage Report and the Central Cook Suburban. These notices gave the date, time, location, and purpose of the meetings. It also provided references to obtain additional information about this specific site, the TMDL Program and other related issues. Individuals and organizations were also sent the public notice by first class mail. An additional stakeholder meeting was held March 31, 2009 (10:00 am) in Plainfield, IL. The draft TMDL Report was available for review at the Elmhurst City Hall and on the Agency's web page at https://www2.illinois.gov/epa/topics/water-quality/watershed-management/tmdls/Pages/reports.aspx.

The first public meeting was attended by approximately 50 people and the second stakeholder meeting was attended by 20 people. The meeting record remained open until midnight, April 17, 2009. A responsiveness summary was developed to address comments (Appendix D).

A public meeting, held jointly with the DuPage River Salt Creek Workgroup bi-monthly meeting, occurred on April 24, 2019 at the village of Lombard village hall to present the draft stage 3 TMDL report and kick-off the 30-day public comment period. Over 60 people attended the meeting. The meeting record remained open through May 24, 2019 and a responsiveness summary was developed to address comments (Appendix D). Original comments are also provided in Appendix D.

2.2 Previous TMDL Development in Watersheds

Previous TMDL reports have been developed and approved in the DuPage River and Salt Creek watersheds. The development of the West Branch DuPage River, East Branch DuPage River, and Salt Creek TMDLs began in 2000. Table 2 summarizes the TMDLs developed for each of these watersheds. In response to these TMDLs, stakeholders in the watershed organized the DuPage River Salt Creek Workgroup (DRSCW), a group that community groups, municipalities, and environmental organizations. DRSCW was formed to better determine the stressors in the aquatic system through a long-term monitoring program and develop and implement viable implementation projects. For more information on this group, please visit their website at <u>www.drscw.org</u>.

TMDL Project	TMDL Approval	Impaired Segments Addressed by TMDL	Pollutants Addressed by TMDL	Notes
East Branch DuPage	2004	GBL-05	Chloride ^a , Ammonia, 5-day Carbonaceous Biochemical Oxygen Demand	33% reduction in chloride required
River		GBL-10	Chloride ^a , Ammonia, 5-day Carbonaceous Biochemical Oxygen Demand	33% reduction in chloride required
		GBL-08	Ammonia, 5-day Carbonaceous Biochemical Oxygen Demand	Multiple scenarios provided to meet TMDL requiring a combination of point source load reduction, SOD reduction, increased DO through artificial reaeration, and dam removal
West Branch	2004	GBK-07	Chloride	35% reduction in chloride required
DuPage		GBK-09	Chloride	_
River		GBK-05	Chloride	-
		GBK-12	Chloride	
Salt Creek	2004	GL-03	Chloride ^a ; Ammonia, 5-day Carbonaceous Biochemical Oxygen Demand, Volatile Suspended Solids ^b	8% reduction in chloride required at mouth of Salt Creek
		GL-09	Chloride ^a	8% reduction in chloride required at mouth of Salt Creek
		GL-10	Chloride ^a	8% reduction in chloride required
		GL-19	Ammonia, 5-day Carbonaceous Biochemical Oxygen Demand, Volatile Suspended Solids ^b	Two scenarios provided to meet TMDL: 34-56% reduction in CBOD ₅ ad 38% reduction in NH ₃
		GLA-02	Chloride	41% reduction in chloride required at mouth of Addison Creek
		GLA-04	Ammonia, 5-day Carbonaceous Biochemical Oxygen Demand, Volatile Suspended Solids ^b	Two scenarios provided to meet TMDL: 34-56% reduction in CBOD ₅ ad 38% reduction in NH ₃
		GLB-01	Ammonia, 5-day Carbonaceous Biochemical Oxygen Demand, Volatile Suspended Solids ^b	
		GLBA	Ammonia, 5-day Carbonaceous Biochemical Oxygen Demand, Volatile Suspended Solids ^b	
		RGZX	Ammonia, 5-day Carbonaceous Biochemical Oxygen Demand, Volatile Suspended Solids ^b	

a. One chloride TMDL was set at the mouth of the river to address all chloride impairments.

b. One TMDL was developed to address all dissolved oxygen-impaired segments in the Salt Creek watershed.

3.0 Watershed Characterization

This section describes the general characteristics of the DuPage River/Salt Creek watershed including location, topography, land cover, soil information, population, climate and precipitation, and hydrology. The DuPage River/Salt Creek Watershed is located in northeastern Illinois and is approximately 520 mi² (332,600 acres). The watershed includes the DuPage River (USGS HUC 0712000408) and Salt Creek (USGS HUC 0712000404) which are within Cook, Kendall, Will, Gundy, and DuPage counties. The DuPage River originates from two branches, the East Brach DuPage River and the West Branch DuPage River. The two rivers meet near Bolingbrook to create the main branch of the DuPage River. The main stem of the DuPage River flows approximately 30 miles before the confluence with the Des Plaines River near the town of Channahon, IL. Salt Creek is approximately 40 miles long and drains to the Des Plaines River. The Des Plaines River flows southwest, and after its confluence with the DuPage River, joins the Illinois River, a major tributary of the Mississippi River.

3.1 Topography

Topography influences soil types, precipitation, and subsequently, watershed hydrology and pollutant loading. For the DuPage/Salt Creek watershed, a USGS 30-meter resolution digital elevation model (DEM) was obtained from the Illinois Natural Resources Geospatial Data Clearinghouse to characterize the topography (Figure 3). In general, the watershed is at a higher elevation in the north and west and grades down to a lower elevation in the south or east toward the Des Plaines River, resulting in overall surface water flow from northwest to southeast. There is a ridge that separates the Salt Creek and DuPage River watersheds. The elevation across the DuPage River/Salt Creek Watershed ranges from 974 feet to 475 feet.

The elevation at the Salt Creek headwaters is 895 feet and the stream flows approximately 43 miles before it enters the Des Plaines River (elevation of 607 feet), resulting in a stream gradient of 6.72 feet per mile (0.0013 slope). The elevation at the DuPage River headwaters is 974 feet and flows into the Des Plaines River 63 miles downstream (elevation of 475 feet). The resulting stream gradient is 7.92 feet per mile (0.0015 slopes).

Figure 3. DuPage River/Salk Creek watershed topography.

3.2 Land Cover

Land cover is as dynamic as the water moving throughout a watershed. It is constantly changing and has a large impact on the quality of a watershed. Land cover data for the watershed were extracted from the <u>2011 National</u> <u>Land Cover Database</u> (NLCD). Table 3 and Table 4 summarize the land cover for the DuPage River and Salt Creek watersheds, respectively. Figure 4 shows land cover in the DuPage River/Salt Creek Watershed and indicates that developed land cover is dominant in both sub-watersheds, accounting for 75% of the total area in the DuPage River watershed and 93% in the Salt Creek watershed. In the DuPage River and Salt Creek watersheds, low intensity development is the predominant land cover (40 and 45% of the total land cover, respectively). Agricultural land accounts for 14% of land cover in the DuPage River watershed, but less than 1% in the Salt Creek watershed.

NLCD 2011 Land Cover Classification	Acreage	Percent	Summarized Acreage	Summarized Percentage
Open Water	3,984	2%	3,984	2%
Developed, Open Space	30,846	13%		
Developed, Low Intensity	96,695	39%

3.3 Soils

Soils data and Geographic Information Systems (GIS) files from the Natural Resources Conservation Service (NRCS) were used to characterize soils in the DuPage River and Salt Creek watershed. General soils data and map unit delineations for the country are provided as part of the Soil Survey Geographic (SSURGO) database. Field mapping methods using national standards are used to construct the soil maps in the SSURGO database. Mapping scales generally range from 1:12,000 to 1:63,360; SSURGO is the most detailed level of soil mapping prepared by the NRCS. A map unit is composed of several soil series having similar properties. Identification fields in the GIS coverage can be linked to a database that provides information on chemical and physical soil characteristics. The SSURGO database contains many soil characteristics associated with each map unit.

The SSURGO data were analyzed based on hydrologic group (Figure 5) and K-factor (Figure 6), a coefficient of the Universal Soil Loss Equation. The hydrologic soil group classification identifies soil groups with similar infiltration and runoff characteristics during periods of prolonged wetting. Typically, clay soils that are poorly drained have lower infiltration rates, while well-drained sandy soils have the greatest infiltration rates. USDA has defined four hydrologic soil groups (A, B, C, or D) for soils. Group A soil has high infiltration while D soil has very low infiltration rate. Table 5 summarizes the group characteristics and shows the distribution of hydrologic soil groups. Generally, areas to the east contain a moderate to slow infiltration rate (group C), while areas near the lakes on the western side of the watershed contain both slow (group D) to moderately high infiltration rates (group B).

Hydrologic Soil Group	Runoff Potential	Infiltration Rate
А	Low	High
В	Moderate	Moderate
С	High	Low
D	High	Very Low

A commonly used soil attribute of interest is the K-factor, a coefficient used in the Universal Soil Loss Equation. The K-factor is a dimensionless measure of a soil's natural susceptibility to erosion. Factor values may range from 0 for water surfaces to 1.00 (although in practice, maximum K-factor values do not generally exceed 0.67). Large K-factor values reflect greater potential for soil erodibility.

The compilation of K-factors from the SSURGO data was done in several steps. Soils are classified in the SSURGO database by map unit symbol. Each map unit symbol is made up of components and each component as part of that map unit is further broken down into horizons (or layers). The K-factor was determined by selecting the dominant components in the most surficial horizon per each map unit. The distribution of K-factor values in the DuPage River and Salt Creek watershed is shown in Figure 6. K-factors range from 0.02 to 0.43 in this watershed. Areas with the highest K-factor are dispersed throughout the watershed with the greatest concentration within DuPage County.

Figure 5. DuPage River/Salt Creek watershed hydrologic soil groups.

Figure 6. DuPage River/Salt Creek watershed SSURGO K-Factor.

3.4 Population

Circumstances in the DuPage River/ Salt Creek watershed today are not only the product of the geologic and natural processes that have occurred in the watershed, but also a reflection of human impacts and population growth. Development has changed the watershed's natural drainage system as channelization and dredging have replaced slow moving shallow streams and wetlands. This alteration has affected the way water runs off of the landscape both in increased volume and velocity, resulting in the potential increase in pollutant transport.

In 2000, approximately 4.8 million, people resided in the DuPage River/Salt Creek watershed, roughly 9,250 persons per square mile. The Salt Creek watershed accounts for nearly 80% of the population, but only 40% of the area. Census blocks with the greatest populations occur in the central and southern areas of the DuPage River watershed in Aurora, Naperville, and Joliet. The Chicago Metropolitan Agency for Planning (CMAP) provides population projections by municipality on their website ("Population Forecast"; updated in 2014). Figure 7 depicts the projected percent population change in the watershed from 2010 to 2040. In general, the southern portion of the watershed is expected to have the most growth, with greater than 200% combined growth across smaller municipalities within Kendall and Will counties. The larger municipalities of Plainfield and Shorewood are projected to grow an average of 142 and 13%, respectively. Based on these data, development will grow dramatically in the southern portion of the watershed, but in general, the entire watershed will continue to increase in population over the upcoming years.

Figure 7. DuPage River/Salt Creek watershed population projection.

3.5 Climate

Northeast Illinois has a continental climate with highly variable weather. The temperatures of continental climates are not buffered by the influence of a large waterbody (like an ocean, inland sea or Great Lake). Areas with continental climates often experience wide temperature fluctuations throughout the year. Temperature and precipitation data were obtained from the Illinois State Climatologist Office website. The nearest monitoring station to the DuPage River/Salt Creek Watershed is the City of Wheaton, which is located in the central area of the watershed. For the DuPage River/Salt Creek watershed, the highest temperatures in the summer can range from high 80s to over 100 degrees Fahrenheit and the lowest winter temperatures might range between sub-zero and the teens. Precipitation in the form of rainfall is greatest in the growing season (April through September) (Figure 8).

Climate data were analyzed for the City of Wheaton between the years of 1950 and 2008, although data were not available for all years. The mean high summer temperature was 84.2° F and the mean low temperature in winter was 17.9° F. Mean annual high temperatures were approximately 61° F, while mean annual low temperatures were approximately 40° F (Table 6). Mean monthly precipitation data in Wheaton are displayed in Figure 8. Wheaton receives most of its precipitation in the spring and summer months, with maximum precipitation occurring in June (4.1 inches). The least amount of average rainfall precipitation occurs in February (1.6 inches). Annual total precipitation average was approximately 35.2 inches.

	Average High (°F)	Average Low (°F)	Average Number of Days with High > 90 (°F)	Average Number of Days with Low < 32 (°F)	Mean (°F)
January	31.36	14.63	0.00	28.50	23.02
February	36.35	18.37	0.00	25.13	27.38

Figure 8. Mean Monthly Precipitation in Wheaton, IL.

3.6 Hydrology

Understanding how water moves and flows is an important component of understanding a watershed. All of the parameters listed in the previous sections (i.e., topography, soils, and precipitation) impact the hydrology of a watershed. Hydrological data are available from the USGS website. The USGS maintains stream gages throughout the U.S. and it monitors conditions such as gage height and stream flow, and at some locations, precipitation and water quality (Figure 9).

Point sources, described in Section 5.3, create effluent-dominated conditions in the watershed during low flow periods. Effluent dominated streams may be high in nutrients and other pollutants, however the effluent also provides a steady baseflow for the river. Streamflow data collected by the USGS at station 5540500 (area-weighted to the mouth of the DuPage River) was used in combination with flow records provided by the permitted point sources (2013 - 2015) in the watershed to determine the approximate percentage of flow that is effluent under various flow conditions. The analysis does not take into account any loss of flow through the system, but assumes that all point source discharges are delivered to the outlet of the watershed. As summarized in Table 7, more than half of the flow in the River is effluent under mid-range and drier conditions.

Flow Category	Median Flow (cfs)	% Time Flow is Exceeded	% of River that is Point Source Effluent
Low Flows	145	95%	>100%
Dry Conditions	211	75%	85%
Mid-Range Flows	322	50%	56%
Moist Conditions	554	25%	32%
High Flows	1,485	5%	12%

Table 7. Approximate	percent of flow attributed to	point source effluent
----------------------	-------------------------------	-----------------------

Figure 9. DuPage River/Salt Creek watershed USGS gaging stations.

Dams also influence hydrologic and water quality conditions throughout the watershed (Figure 10). Dams regulate the depth of water in the river and affect flows. They can also serve to prevent fish migration and contribute to low dissolved oxygen conditions due to slow moving or stagnant waters in upstream pools. Six dams have been removed or modified to address these issues.

Four gage stations within the DuPage River/Salt Creek Watershed were chosen to evaluate stream flow: East Branch of DuPage River at Downers Grove, IL (05540160), West Branch of DuPage River at Naperville, IL (05540130), DuPage River at Shorewood, IL (05540500), and Salt Creek at Western Springs, IL (05531500). The Salt Creek gage is located just upstream from the Addison Creek confluence near the confluence with the Des Plaines River. The East Branch is located upstream of the confluence with the West Branch. The West Branch of the DuPage River gage station is located immediately upstream of the confluence with the East Branch. Finally, the DuPage River at Shorewood is located immediately upstream of the confluence of the DuPage River main stem and the Des Plains River. Figure 9 shows the location of these four USGS gages, and others, throughout the watershed. Figure 11 depicts the stream flow measured at Salt Creek for the period of 1945 to 2007. The drainage area upstream of this gage was 115 square miles. The highest average monthly stream flows were measured in April (233.0 cubic feet per second [cfs]), while the lowest monthly stream flows were measured in September (93.9 cfs). Overall the highest stream flow for this gage occurs during the late winter and spring months, while low flows occur during the fall. The annual stream flow for the Salt Creek gage was measured at about 136.8 cfs.

The East Branch DuPage gage drains an area of 26.6 square miles, and data at this gage exist from 1989 to 2007. Over this period the average stream flow of the East Branch was 49.5 cfs (Figure 12). Similar to the Salt Creek gage, stream flows were highest in the late winter and spring months with lower flows in the fall. Maximum average monthly flows occurred in April (69.0 cfs) while lowest average monthly flows occurred in September (35.2 cfs).

Figure 13 displays the stream flow measured at the West Branch DuPage River for the period ranging from 1988 to 2007. The drainage area upstream of this gage was 123 square miles and the highest average monthly stream flows at the West Brach were measured in April (230.6 cfs). Minimum average monthly stream flows of 102.0 cfs were measured in September. The annual stream flow for the West Branch gage was approximately 152.9 cfs.

Data from the main stem of the DuPage River gage exist from 1940 to present. This gage drains an area of 324 square miles and over the duration of its existence the average stream flow of the DuPage was 307.3 cfs (Figure 14). Peak stream flows occur in the late winter and spring months, with lower flows in the fall. Maximum monthly flow occurred in April (517.7 cfs) while lowest monthly flows were measured in September (189.9 cfs).

3.7 Watershed Studies and Other Watershed Information

There are a number of organizations and counties in the DuPage River and Salt Creek watersheds that have collected and developed information and studies that are pertinent to this TMDL. For reports and studies concerning the DuPage River and Salt Creek watersheds, please visit the DuPage River Salt Creek Workgroup (http://www.drscw.org/) and the Lower DuPage River Watershed Coalition (http://www.dupagerivers.org/). The websites contains reports, data and additional links related to this watershed. In addition, DuPage County has conducted several watershed planning and implementation projects (http://www.dupageco.org/swm/) and Chicago Metropolitan Area Planning is currently conducting watershed planning activities in the Salt Creek watershed (http://www.cmap.illinois.gov/programs-and-resources/lta/lower-salt-creek._Section 8.0 provides additional information on watershed partners and organizations.

In addition, Illinois EPA conducted Stage 2 monitoring activities in the West Branch and Mainstem DuPage River, results are included in Appendix B of this TMDL.

4.0 Applicable Water Quality Standards and TMDL Endpoints

Water pollution control programs are designed to protect the beneficial uses of the water resources within the state. Each state has the responsibility to set water quality standards (WQS) that protect these beneficial uses, also called designated uses. Illinois waters are designated for various uses including aquatic life, primary contact (e.g., swimming, water skiing), secondary contact (e.g., boating, fishing), industrial use, drinking water, food-processing water supply and aesthetic quality. Illinois' WQS provide the basis for assessing whether the beneficial uses of the state's waters are being attained.

4.1 Illinois Pollution Control Program

The Illinois Pollution Control Board (IPCB) is responsible for setting WQS to protect designated uses. The federal Clean Water Act requires states to review and update WQS every three years. Illinois EPA, in conjunction with USEPA, identifies and prioritizes those standards to be developed or revised during this three-year period. The IPCB has established four primary sets (or categories) of narrative and numeric water quality standards for surface waters: general use; public and food processing; secondary contact and indigenous aquatic life; and Lake Michigan basin standards. Each set of standards is intended to help protect various designated uses established for each category.

Illinois EPA is also responsible for developing scientifically based water quality criteria and proposing them to the IPCB for adoption into state rules and regulations. These responsibilities were subsequently assumed by the Illinois Department of Energy and Natural Resources who, in July 1995, became part of the Illinois Department of Natural Resources. The Illinois WQS are established in the Illinois Administrative Rules Title 35, Environmental Protection; Subtitle C, Water Pollution; Chapter I, Pollution Control Board; Part 302, Water Quality Standards.

4.2 Designated Uses

The waters of Illinois are classified by designated uses (Table 8). Designated uses applicable to the DuPage River/Salt Creek watershed TMDL include aquatic life and primary contact recreation. The corresponding water quality standard classification for these designated uses is the General Use Standard. The General Use classification is defined by IPCB as: The General Use standards will protect the state's water for aquatic life, wildlife, agricultural use, secondary contact use and most industrial uses and ensure the aesthetic quality of the state's aquatic environment. Primary contact uses are protected for all General Use waters whose physical configuration permits such use.

Illinois EPA Designated Uses	Illinois waters where Designated Use and Standards apply	Applicable Illinois Water Quality Standards
Aquatic Life	Streams, Inland Lakes	General Use Standards
	Lake Michigan Basin waters	Lake Michigan Basin Standards
Aesthetic Quality	Inland Lakes	General Use Standards
	Lake Michigan Basin Waters	Lake Michigan Basin Standards
Indigenous Aquatic Life	Specific Chicago area Waters	Secondary Contact and Indigenous Aquatic Life Standards
Primary Contact	Streams, Inland Lakes	General Use Standards
	Lake Michigan Basin Waters	Lake Michigan Basin Standards
Secondary Contact	Streams, Inland Lakes	General Use Standards
	Lake Michigan Basin Waters	Lake Michigan Basin Standards
	Specific Chicago area Waters	Secondary Contact and Indigenous Aquatic Life Standards
		Public and Food Processing Water Supply Standards
Fish Consumption	Streams, Inland Lakes	General Use Standards
	Lake Michigan Basin Waters	Lake Michigan Basin Standards
	Specific Chicago Area Waters	Secondary Contact and Indigenous Aquatic Life Standards

4.3 Applicable Illinois Water Quality Standards

Environmental regulations for the State of Illinois are contained within the Illinois Administrative Code, Title 35. Specifically, Title 35, Part 302 contains water quality standards promulgated by the Illinois Pollution Control Board. This section presents the standards applicable to impairments within the study area. Water quality standards to be used for water quality assessment (Section 5.0) and TMDLs (Section 7.0) in the DuPage River/Salt Creek watersheds are provided in Table 9.

Parameter	Units	General Use Water Quality Standard	
Water Quality Standards for Impairment Assessment and TMDL Development			
Chloride	mg/L	500	
Dissolved Oxygen ^a	mg/L	For most waters:	
		March-July > 5.0 min. & > 6.0 7-day mean	
		Aug-Feb > 3.5 min, > 4.0 7-day mean, & > 5.5 30-day mean	
		For waters with enhanced protection (i.e., GB-16):	
		March-July > 5.0 min & > 6.25 7-day mean	
		Aug-Feb > 4.0 min, > 4.5 7-day mean, & > 6.0 30-day mean	
Fecal Coliform	count/100 mL	400 in <10% of samples ^b during May-October	
		Geometric mean < 200 ° during May-October	
Wate	er Quality Standa	ards for Impairment Assessment Only	
рН	s.u.	Within the range of 6.5 – 9.0 except for natural causes	
Nickel, Dissolved	µg/L	Acute standard: $e^{A+Bln(H)} \times 0.998$, where A=0.5173 and	
		B=0.8460; H=hardness	
		Chronic standard: $e^{A+Bln(H)} \times 0.997$, where A=-2.286 and	
		B=0.8460; H=hardness	
Copper, Dissolved	µg/L	Acute standard: $e^{A+Bln(H)} \times 0.960$, where A=-1.464 and	
		B=0.9422; H=hardness	
		Chronic standard: $e^{A+Bln(H)} \times 0.960$, where A=-1.465 and	
		B=0.8545; H=hardness	

Table 9. Summary of water quality standards

a. Applies to the dissolved oxygen concentration in the main body of all streams, in the water above the thermocline of thermally stratified lakes and reservoirs, and in the entire water column of unstratified lakes and reservoirs. Additional dissolved oxygen criteria are found in 35 III Adm. Code 302.206, including the list of waters with enhanced dissolved oxygen protection and methods for assessing attainment of dissolved oxygen minimum and mean values.

b. Standard shall not be exceeded by more than 10% of the samples collected during any 30-day period.

c. Geometric mean based on a minimum of 5 samples taken over not more than a 30-day period.

DuPage River segment GB-16 is designated for dissolved oxygen enhanced protection according to 35 III Adm. Code 302.206. Waters with enhanced protection have a more stringent dissolved oxygen standard than all other waters of the State. These waters were chosen based on the potential biota (fish early life stages present) and the dissolved oxygen needed for these biota to thrive. All other dissolved oxygen impaired waters in the DuPage River and Salt Creek watersheds are not considered enhanced protection waters and the standard for "most waters" applies.

Due to limited resources, fecal coliform bacteria is not normally sampled at a frequency necessary to apply the General Use standard, i.e., at least five times per month during May through October. Therefore, assessment guidelines are based on application of the standard when sufficient data are available to determine standard exceedances; but, in most cases, attainment of the *primary contact* use is based on a broader methodology intended to assess the likelihood that the General Use standard is being attained. To assess the *primary contact* use, Illinois EPA uses all fecal coliform bacteria from water samples collected in May through October, over a five-year period. Based on these water samples, geometric means and individual measurements of fecal coliform bacteria concentration thresholds in Table 10. To apply the guidelines, the geometric mean of fecal coliform bacteria concentration is calculated from the entire set of May through October water samples, across the five years. No more than 10% of all the samples may exceed 400/100 ml for a water body to be considered Fully Supporting.

Degree of Use Support	Guidelines No exceedances of the fecal coliform bacteria standard in the last five years <u>and</u> the geometric mean of all fecal coliform bacteria observations ≤200/100 ml, <u>and</u> ≤10% of all observations exceed 400/100 ml.		
Fully Supporting (Good)			
Not Supporting (Fair)	One exceedance of the fecal coliform bacteria standard in the last five years (when sufficient data is available to assess the standard) <u>or</u> The geometric mean of all fecal coliform bacteria observations in the last five years <200/100 ml, <u>and</u> >10% of all observations in the last five years exceed 400/100 ml		
	or The geometric mean of all fecal coliform bacteria observations in the last five years >200/100 ml, and <25% of all observations in the last five years exceed 400/100 ml.		
Not Supporting (Poor)	More than one exceedance of the fecal coliform bacteria standard in the last five years (when sufficient data is available to assess the standard) or The geometric mean of all fecal coliform bacteria observations in the last five years >200/100 ml, and >25% of all observations in the last five years exceed 400/100 ml		

4.4 TMDL Endpoints

In order for a waterbody to be listed as Fully Supporting, it must meet all of its applicable designated uses. Because WQS are designed to protect those designated uses, a pollutant's numeric WQS is therefore used as the target or endpoint for establishing a TMDL. Table 11 summarizes the endpoints that will be used in the TMDL development for the DuPage River/Salt Creek watershed, only those segments receiving TMDLs are included in this table. All parts of each standard (e.g., two parts for fecal coliform) are required to be met.

Waterbody ID	Waterbody Name	TMDL Pollutant(s)	TMDL Endpoint
		Chloride	<500 mg/L
IL_GB-11 DuPage River	DuPage River	Fecal Coliform	<400 count/100 ml in <10% of samples and <200 count/100ml (30-day geometric mean of at least 5 samples)
		Dissolved Oxygen	March-July > 5.0 min & > 6.25 7-day mean Aug-Feb > 4.0 min, > 4.5 7-day mean, & > 6.0 30-day mean
IL_GB-16	DuPage River	Fecal Coliform	<400 count/100 ml in <10% of samples and <200 count/100ml (30-day geometric mean of at least 5 samples)
IL_GBK-05	West Branch DuPage River	Fecal Coliform	<400 count/100 ml in <10% of samples and <200 count/100ml (30-day geometric mean of at least 5 samples)
IL_GBK-09	West Branch DuPage River	Fecal Coliform	<400 count/100 ml in <10% of samples and <200 count/100ml (30-day geometric mean of at least 5 samples)
	West Branch DuPage River	Dissolved Oxygen	March-July > 5.0 min. & > 6.0 7-day mean Aug-Feb > 3.5 min, > 4.0 7-day mean, & > 5.5 30-day mean

IL_GL-19	Salt Creek	Fecal Coliform	<400 count/100 ml in <10% of samples and <200 count/100ml (30-day geometric mean of at least 5 samples)
IL_GLA-02	Addison Creek	Fecal Coliform	<400 count/100 ml in <10% of samples and <200 count/100ml (30-day geometric mean of at least 5 samples)

5.0 Water Quality Assessment

An important step in the TMDL development process is the review of water quality conditions, particularly data and information used to list segments. Examination of water quality monitoring data is a key part of defining the problem that the TMDL is intended to address. This section provides a brief review of available water quality information for all impaired waters. All relevant available data are presented below; however only recent data are used when evaluating impairment status. Each data point was reviewed to ensure the use of quality data in the analysis below.

5.1 Water Quality Data

Water quality data for impaired streams (excluding LRS pollutants and those streams being delisted in 2016) in the DuPage River/Salt Creek Watershed are collected by many agencies (Table 12). Figure 15 through Figure 17 show the water quality stations within the watershed that contain relevant data. Data analysis focused on available data collected since the year 2000. The information presented in this section is a combination of Water Quality Portal - formerly known as (USEPA Storage and Retrieval database - STORET) and data from the Illinois EPA database, Wheaton Sanitary District (WSD), Metropolitan Water Reclamation District of Greater Chicago (MWRDGC, now MWRD), US Geological Survey (USGS), and DRSCW.

5.1.1 Fecal Coliform

Figure 18 through Figure 20 contain the available fecal coliform data. Data are available from the years indicated in the time series graphs; Table 13 summarizes the data used in the analysis. The WQS for fecal coliform is a 200 cfu/100ml geometric mean based on a minimum of five samples taken over any 30-day period between May and October and a 400 cfu/100ml maximum not to be exceeded in more than 10% of samples taken during any 30-day period between May and October. Due to the unlikelihood of having five fecal coliform samples per month upon which to judge compliance, a single exceedance of 400 cfu/100 ml will be interpreted as a violation of the WQS for assessment purposes. Fecal coliform impairment is verified for all of the listed segments.

Segment	Stations	Data	No. of	Violations >400	Min	Max	Average	Median

Figure 20. Fecal coliform time series for GL, GL-09, GL-10, GL-19, and GLA-02.

5.1.2 Dissolved Oxygen

The dissolved oxygen WQS for all segments except GB-16 is a 5.0 mg/L instantaneous minimum for March through July and 3.5 mg/L for August through February. Segment GB-16 is subject to enhanced protection so the WQS is a 5.0 mg/L instantaneous minimum for March through July and 4.0 mg/L for August through February. Three waterbody segments are listed as impaired due to low dissolved oxygen. Data from 2004 through 2016 were evaluated (Table 14).

Figure 21 contains summary information for Illinois EPA monthly dissolved oxygen data for GB-16 enhanced waterbody, and Figure 22 contains continuous hourly monitoring data for GB-16. Discrete dissolved oxygen measurements taken after 2006 by the Lower DuPage River Watershed Coalition confirm the impairment (Figure 23). The DRSCW collected continuous dissolved oxygen data during low flow summer conditions in 2016 at GBK-14 (Springsmuth Road) and at two sites along GBKA (Figure 24, Figure 25). These data clearly show impairment of the streams.

Sediment oxygen demand (SOD) data were collected as part of a Stage 2 monitoring effort, see Appendix B for the full Stage 2 report. Collected SOD data indicated high levels of SOD in the watershed ranging from 2.45 g/m2/day at Hanover Park (the upstream sampling location on the West Branch DuPage River) to 6.19 g/m2/day at West Chicago at ambient temperature. SOD is the sum of all biological and chemical processes in sediment that utilize oxygen.

Segment	Stations	Data Years	Observations	Violations	Minimum mg/L
GB-16	IEPA GB-08 IEPA GB-16 ª	2000- 2006	443	28	3.54
GBK-14	DRSCW Springsmuth Site ^a	2016	Continuous between 9/1/2016- 9/7/2016	Yes	1.06
GBKA	DRSCW School Site ^a	2016	Continuous between 7/26/2016- 8/2/2016	Yes	2.66

Table 14. Dissolved oxygen data summary

Figure 24. 2016 dissolved oxygen data for GBKA provided by DRSCW.

Figure 25. 2016 dissolved oxygen data for GBK-14 provided by DRSCW.

5.1.3 pH

The WQS dictates an acceptable pH range between 6.5 and 9.0 s.u. Four segments are listed as impaired; three of these segments are being delisted on the 2016 303(d) list including GBK-14, GBL-08, and GBL-10 and are therefore not evaluated. Table 15 summarizes the available data for the remaining segment GL-10. Figure 26 displays pH data available from 2004–2013 for GL-10. All pH data on GL-10 meet the pH water quality criteria, based on these data the waterbody is not impaired.

Table 15. pH data summary

Sagmont	Stations	Data Years	Observations	Violations	Min	Max

GL-10	MWRDGC WW_80, DRSCW SC42, SC43	2001-2007	97	0	6.6	8.2

Figure 26. pH time series for GL-10.

5.1.4 Chloride

Two segments are listed as impaired for chloride: GBKA and GB-11. The general use water quality standard for chloride is 500 mg/L. Table 16 and Figure 27 summarize the available chloride data.

Two chloride exceedances have been recorded on GB-11 (Figure 27). Data at GBKA-01, located immediately downstream of GBKA, are used to assess GBKA for impairment. There were no monitored water quality standard exceedances on this reach (Figure 28). A chloride TMDL has also been approved downstream of GBKA on GBK-05 which addresses chloride sources in the entire watershed, including GBKA. The data do not indicate impairment of GBKA, and no chloride TMDL is proposed for this segment.

Segment	Stations	Data	Observations	Violations	Min	Max	Average	Median
Segment	Stations	Years	Observations	VIOIALIONS	mg/L			
GB-11	GB-08,11,18, DRSCW LD06, 07, 08, 05540500	1977 - 2013	366	5	19	1,680	193	172
GBKA	WB10, WB11, WB26, WSD DOWN, WSD UP	2004 - 2013	33	0	34	205	144	150

 Table 16. Chloride data summary

Figure 27. Chloride time series for GB-11, provided by Illinois EPA.

Figure 28. Chloride time series for GBKA (measured at GBKA-01), provided by Illinois EPA.

5.1.5 Copper

One segment is listed as impaired for copper: Spring Brook (GBKA-01), however this segment is being delisted as part of the 2016 303(d) list. No water quality analysis is provided for this segment.

5.1.6 Nickel

Two segments are listed for nickel impairment within the DuPage River/Salt Creek Watershed: GL-10 on the main stem of Salt Creek and GLA-02 on Addison Creek. The WQS is based on dissolved nickel and is hardness dependent. Both a chronic and acute standard are applicable. The median hardness value for each impaired reach was used to derive applicable water quality targets. In this case, the acute standard for IL_GL-10 is 160 μ g/L, and the chronic standard is 9.7 μ g/L. The acute standard for IL_GLA-02 is 172 μ g/L, and the chronic standard is 9.7 μ g/L.

Table 17 summarizes available nickel data. Data collected for GL-10 and GLA-02 indicate that the dissolved nickel water quality standard was not violated during the monitoring period between 2004 and 2013 on either reach (Figure 29 and Figure 30). There were no monitored exceedances of the acute or chronic standard (based on four consecutive samples) in the streams. The available data do not indicate impairment of these segments; TMDLs will not be developed. Concurrent monitoring of both dissolved nickel and hardness could be used to justify delisting of these segments.

Segment	Stations	Data	Observa-	Violations (acute	Violations (chronic	Min	Max	Average	Median
		Years	tions	standard)	standard)		μg/L		
GL-10	WW_80	2004- 2007	48	0	0	0	8.4	1.3	0
GLA-02	GLA-02	2004- 2013	80	0	0	0.56	13ª	3.8	2.5

Table 17. Dissolved nickel data summary

a. Two of the individual samples were greater than the chronic standard (10.4 µg/L; however, the standard was not violated because the average of four consecutive samples did not exceed the standard.

Figure 29. Nickel time series for GL-10.

Figure 30. Nickel time series for GLA-02.

5.2 Pollutants of Concern for TMDL Development

Based on the water quality data provided in the previous section, pollutants of concern further evaluated in this TMDL include fecal coliform, chlorides, and parameters influencing dissolved oxygen levels. Dissolved oxygen in streams can be affected by biochemical oxygen demand, phosphorus, ammonia, and sediment oxygen demand in addition to non-pollutant causes such as a lack of reaeration. These pollutants can originate from an array of sources including point and nonpoint sources. Eutrophication (high levels of algae) is also often linked directly to low dissolved oxygen conditions and high pH, and therefore nutrients are also a pollutant of concern. The following sections provide a summary of potential point and nonpoint sources that contribute to the impaired waterbodies.

5.3 Point Sources

Point source pollution is defined by the Federal Clean Water Act (CWA) §502(14) as:

"any discernible, confined and discrete conveyance, including any ditch, channel, tunnel, conduit, well, discrete fissure, container, rolling stock, concentrated animal feeding operation [CAFO], or vessel or other floating craft, from which pollutants are or may be discharged. This term does not include agriculture storm water discharges and return flow from irrigated agriculture."

Under the CWA, all point sources are regulated under the NPDES program. A municipality, industry, or operation must apply for an NPDES permit if an activity at that facility discharges wastewater to surface water. Point sources can include facilities such as municipal wastewater treatment plants (WWTPs), industrial facilities, CAFOs, or regulated storm water including municipal separate storm sewer systems (MS4s). There are no permitted CAFOs in the watershed.

5.3.1 NPDES Permitted Facilities

NPDES facilities within the watershed include municipal and industrial wastewater treatment plants (Figure 31). Nutrients and other oxygen-demanding substances found in WWTP discharge can contribute to low dissolved oxygen conditions in the watershed. WWTPs are also a source of fecal coliform and chloride.

Table 18 and Table 19 summarize the individual NPDES permitted facilities within the DuPage Salt Creek watershed as provided by Illinois EPA. The average and maximum design flow for each facility are also listed when available. These facilities are or will be required to reduce their total phosphorus loadings to comply with an existing 1 mg/l total phosphorus effluent concentration limit in wastewater as part of special conditions set forth in NPDES permits issued by the Illinois EPA; these reductions will help to meet dissolved oxygen conditions in the Lower DuPage River and improve instream phosphorus conditions throughout the watershed. In addition to a phosphorus limit, facilities are required to comply with a series of special conditions that addresses watershed chloride reduction and in-stream habitat as part of their NPDES permits (Appendix G).

Eight facilities also have permitted combined sewer overflows (CSOs) in the DuPage River Salt Creek watershed (Table 19 and Figure 32). CSOs are the result of wet weather, which is not the critical condition for dissolved oxygen. When CSOs occur, wastewater enters rivers and streams untreated, discharging pollutants including fecal coliform, solids, chloride, and phosphorus. CSOs are summarized based on the maximum CSO flow during the time period 2013–2015, as reported in Illinois EPA's discharge monitoring reports (DMRs) or as provided by the permitted entity. The status of Long-Term Control Plans (LTCPs) is also provided. One facility is exempt from developing a LTCP (GLENBARD WW AUTH-LOMBARD) because due to CSO controls, permittee has achieved 4 overflows/year as required under the Presumption Approach, and, as allowed in Special Condition 10.10b in its permit, is exempt from developing a LTCP unless required to develop and implement by Special Condition 10.10c. Four facilities are part of the MWRD's Tunnel and Reservoir Plan (TARP) System, which conveys combined sewer flow through tunnels to storage reservoirs. After an event is over, the water in the reservoirs is pumped to a water reclamation plant, treated, and discharged to surface waters. These facilities are not required to submit separate LTCPs.

Two WWTPs have disinfection exemptions in the watershed that allow a facility to discharge wastewater without disinfection. One of the facilities discharges downstream of the impaired segments (IL0021121). The other facility discharges to a tributary of Salt Creek just upstream of impaired segment GL-09 (IL0052817). Facilities with disinfection exemptions may be required to provide Illinois EPA with updated information to demonstrate compliance with these requirements and facilities directly discharging into a fecal-impaired segment may have their disinfection exemption re-evaluated through future NPDES permitting actions.

Due to the large number of facilities draining to fecal coliform impairments, facilities identified as sources of fecal coliform by Illinois EPA are identified in Table 18. These facilities have a fecal coliform limit included in their NPDES permit, are a CSO, or have a fecal coliform monitoring requirement in the case of one WWTP (IL0052817).

a. Maximum CSO volume during February 2014 event based on 2013-2015 discharge report provided by facility.

b. Maximum CSO volume based on reported average annual discharge of 154 million gallons provided by facility. Four events are assumed each year (154 MG per year / 4 events = 38.5 MGs per event).

Figure 31. Existing NPDES dischargers in the DuPage River/Salt Creek watershed.

Figure 32. Location of CSO Outfalls for each facility in Table 19.

Facilities that discharge directly to fecal coliform-impaired segments addressed with this TMDL are required to comply with permit requirements as part of this TMDL. Violations of fecal coliform limits were identified at several of these WWTPs between 2013 and 2015 based on discharge monitoring reports (Table 20). There is also one combined sewer overflow (CSO) in the watershed discharging to a fecal coliform-impaired segment along the East Branch DuPage River (Glenbard Wastewater Authority-Lombard). Addressing this CSO is needed to meet fecal coliform water quality standards in the River.

The Glenbard Wastewater Authority-Lombard CSO also discharges into the East Branch DuPage River, which is impaired for dissolved oxygen and chloride. An existing TMDL addresses these impairments and is expected to bring the East Branch DuPage River into compliance with water quality standards prior to the East Branch DuPage River discharging in the mainstem DuPage River. As described in Section 6.0, both the dissolved oxygen TMDL for GB-16 and the chloride TMDL for GB-11 assume that the East Branch DuPage River is meeting standards, per the existing TMDLs.

a. This facility does not have a fecal coliform limit in its permit, exceedances are of the 400 cfu/100 mL water quality standard.

5.3.1 Municipal Separate Storm Sewer Systems

Stormwater, while not an actual source of pollutants itself, acts as an important delivery mechanism of multiple sources of each pollutant. The sources of pollutants in stormwater are many including decaying vegetation (leaves, grass clippings, etc.), pet and wildlife waste, soil, deposited particulates from the air, road salt, and oil and grease from vehicles. The most significant sources of pollutants include chloride from de-icing agent used for winter road maintenance (i.e., road salt) and fecal coliform conveyed in stormwater runoff from pet and wildlife waste. In urban areas, non-permitted cross connections between sanitary sewers and storm sewers can also occur. For example, accidental connections between sewer lines of private homes or businesses may occur during construction and go unnoticed. These discharges may also be considered point sources.

Under the NPDES program, municipalities serving populations over 100,000 people are considered Phase I MS4 communities. Municipalities serving populations under 100,000 people are considered Phase II communities. Within Illinois, Phase II communities are allowed to operate under the statewide General

Stormwater Permit (ILR40) which first requires dischargers to file a Notice of Intent, acknowledging that discharges shall not cause or contribute to a violation of water quality standards. To assure pollution is controlled to the maximum extent practical, regulated entities operating under the State General Permit (ILR40) are required to implement six control measures including:

- Public education and outreach on storm water impacts
- Public involvement and participation
- Illicit discharge detection and elimination
- Construction site storm water runoff control
- Post construction storm water management in new development and redevelopment
- Pollution prevention/good housekeeping for municipal operations

The entire project area is regulated under the State General Permit (ILR40). The Illinois Department of Transportation and Illinois Toll Way are regulated road authorities; counties are also regulated MS4s and are responsible for permitting within unincorporated portions of the county. A list of MS4s is provided in Appendix J.

MS4 sources of chloride are primarily related to de-icing agents being applied to sidewalks, parking lots, and roads. A chloride reduction study completed for the DRSCW found that the application of road salt for snow removal was the primary contributor to chloride water quality standard exceedances in the watershed (CDM 2007).

Potential sources of fecal coliform in MS4 runoff include domestic pet and wildlife waste. When pet waste is not disposed of properly, it can be picked up by runoff and washed into nearby waterbodies. Waste from pets can be a source of concern in watersheds with a higher density of developed area. Compared to rural areas, developed areas have higher densities of pets and a higher delivery of waste to surface waters due to connected impervious surfaces. Wildlife such as birds and raccoons can be another source of fecal coliform bacteria.

Low dissolved oxygen can be the result of biochemical oxygen demand (BOD) loads. BOD is the measure of oxygen demand from both biological and chemical processes. Primary sources of BOD from MS4s are organics such as grass clippings and leaves and nutrients from fertilizers. Nutrients can result in algae and macrophyte growth, which in turn increases organic matter in the stream and BOD from biological processes resulting in less available dissolved oxygen.

5.4 Nonpoint Sources

The term nonpoint source pollution is defined as any source of pollution that does not meet the legal definition of point sources. Nonpoint source pollution typically results from overland stormwater runoff that is diffuse in origin, as well as background conditions. It should be noted that stormwater collected and conveyed through a regulated MS4 is considered a controllable point source. Runoff from nonregulated areas, in this case limited to agricultural areas, is the main nonpoint source of pollutants to impaired streams. In addition, sediment oxygen demand in streams also contributes to low dissolved oxygen conditions. Septic systems can also be a source of nonpoint pollution if they are not maintained properly. A pilot study was completed in 2012 to develop a methodology to create an inventory of septic system (CDM Smith 2012) and is available on Illinois EPA's TMDL Reports website: https://www2.illinois.gov/epa/topics/water-quality/watershed-management/tmdls/Pages/reports.aspx.

Agricultural areas can have significant effects on water quality if proper best management practices are not in place, specifically contributing to high biochemical oxygen demand and nutrients that can affect the dissolved oxygen conditions in streams. Similar to MS4 permitted stormwater water (Section 5.3.2), nonpoint stormwater runoff acts as a delivery mechanism for several sources of pollutants. During wet-weather events (snowmelt and rainfall), pollutants including fecal coliform, chloride and nutrients from fertilizer application, and oxygen-demanding substances (e.g., decaying vegetation) are incorporated into stormwater runoff and can be delivered to downstream waterbodies. Fertilizers used for cropland typically are considered a potential source of nutrient enrichment in waterbodies which results in increased BOD and is linked to lower dissolved oxygen conditions.

Sediment oxygen demand is a result of the biological consumption of organic material at the sediment-water interface and is a component of BOD, however because it is a result of biochemical processes in the stream itself, it is considered a nonpoint source pollutant.

6.0 TMDL Approach and Methods

Table 21 summarizes the TMDL that are being completed based on water quality evaluation and updated 303(d) listings. The following listed impairments have been proposed for delisting as part of the draft 2016 303(d) list, and therefore no TMDLs are prepared:

- pH in the East Branch DuPage River, segments GBL-08 and GBL-10
- pH in the West Branch DuPage River, segment GBK-14
- Copper in Spring Brook, segment GBKA-01

The following impairments were determined to be not exceeding water quality standards based on the most recent data, and therefore no TMDLs are being prepared:

- Nickel in Salt Creek, segment GL-10
- pH in Salt Creek, segment GL-10
- Nickel in Addison Creek, segment GLA-02
- Chloride in Spring Brook, segment GBKA

And finally, Illinois EPA is not completing LRSs to address phosphorus or sediment in this watershed. This is primarily due to the presence of the DuPage River Salt Creek Work Group and the Lower DuPage River Watershed Coalition and their high level of activity addressing water quality and impairments in the watershed.

Waterbody ID	Waterbody Name	Designated Use	TMDL Pollutant(s)

Table 21. Final list of TMDLs being prepared

The following sections discuss the methodology used for the development of TMDLs for the DuPage River/Salt Creek watershed. While a detailed watershed modeling approach can be advantageous, a simpler approach is often able to efficiently meet the requirements of a TMDL and yet still support a site-specific implementation plan. The final approach was determined in consultation with Illinois EPA based on the following factors:

- Fundamental requirements of a defensible and approvable TMDL
- Data availability
- Fund availability
- Public acceptance
- Complexity of waterbody

6.1 Modeling Approach for Fecal Coliform and Chloride

A waterbody's loading capacity represents the maximum rate of loading of a pollutant that can be assimilated without violating water quality standards (40 CFR 130.2(f)). In the case of fecal coliform, a TMDL is developed or both parts of the water quality standard (see Section 4.0) and both parts must be met. Establishing the relationship between in-stream water quality and source loading is an important component of TMDL development. It allows the determination of the relative contribution of sources to total pollutant loading and the evaluation of potential changes to water quality resulting from implementation of various management options.

A duration curve approach is used to evaluate the relationships between hydrology and water quality and calculate the loading capacity for fecal coliform and chloride. The primary benefit of duration curves in TMDL development is to provide insight regarding patterns associated with hydrology and water quality concerns. The duration curve approach is particularly applicable because water quality is often a function of stream flow. The use of duration curves in water quality assessment creates a framework that enables data to be characterized by flow conditions. The method provides a visual display of the relationship between stream flow and water quality.

Allowable pollutant loads can be determined through the use of load duration curves. Discussions of load duration curves are presented in *An Approach for Using Load Duration Curves in the Development of TMDLs* (U.S. EPA 2007a). This approach involves calculating the allowable loadings over the range of flow conditions expected to occur in the impaired stream by taking the following steps:

- 1. A flow duration curve for the stream is developed by generating a flow frequency table and plotting the data points to form a curve. The data reflect a range of natural occurrences from extremely high flows to extremely low flows.
- 2. The flow curve is translated into a load duration (or TMDL) curve by multiplying each flow value (in cubic feet per second) by the water quality standard for a contaminant (mg/L or count/100 mL), then multiplying by conversion factors to yield results in the proper unit (i.e., pounds per day or count/day). The resulting points are plotted to create a load duration curve.
- 3. Each water quality sample is converted to a load by multiplying the water quality sample concentration by the average daily flow on the day the sample was collected. Then, the individual loads are plotted as points on the TMDL graph and can be compared to the water quality standard, or load duration curve.
- 4. Points plotting above the curve represent deviations from the water quality standard/target and the daily allowable load. Those plotting below the curve represent compliance with standards and the daily allowable load. Further, it can be determined which locations contribute loads above or below the water quality standard.
- 5. The area beneath the TMDL curve is interpreted as the loading capacity of the stream. The difference between this area and the area representing the current loading conditions is the load that must be reduced to meet water quality standards.
- 6. The final step is to determine where reductions need to occur. Those exceedances at the right side of the graph occur during low flow conditions, and may be derived from sources such as illicit sewer connections. Exceedances on the left side of the graph occur during higher flow events, and may be derived from

sources such as runoff. Using the load duration curve approach helps to determine which implementation practices are most effective for reducing loads on the basis of flow regime.

The flow regimes are typically divided into 10 groups, which can be further categorized into the following five hydrologic zones (U.S. EPA 2007a):

- High flow zone: stream flows that plot in the 0 to 10-percentile range, related to flood flows
- Moist zone: flows in the 10 to 40-percentile range, related to wet weather conditions
- Mid-range zone: flows in the 40 to 60-percentile range, median stream flow conditions
- Dry zone: flows in the 60 to 90-percentile range, related to dry weather flows
- Low flow zone: flows in the 90 to 100-percentile range, related to drought conditions

The duration curve approach helps to identify the issues surrounding the impairment and to roughly differentiate among sources. Table 22 summarizes the general relationship between the five hydrologic zones and potentially contributing source areas (the table is not specific to any individual pollutant). For example, the table indicates that impacts from point sources are usually most pronounced during dry and low flow zones because there is less water in the stream to dilute their loads. In contrast, impacts from channel bank erosion is most pronounced during high flow zones because these are the periods during which stream velocities are high enough to cause erosion to occur.

Contributing source area	Duration Curve Zone						
Contributing Source area	High	Moist	Mid-range	Dry	Low		
Point source				М	Н		
Riparian areas		Н	Н	М			
Stormwater: Impervious		Н	Н	Н			
Combined sewer overflow	Н	Н	Н				
Stormwater: Upland	Н	Н	М				
Field drainage: Natural condition	Н	М					
Bank erosion	Н	М					

Table 22. Relationship between duration curve zones and contributing sources

Note: Potential relative importance of source area to contribute loads under given hydrologic condition (H: High; M: Medium; L: Low).

The load reduction approach also considers critical conditions and seasonal variation in the TMDL development as required by the Clean Water Act and U.S. EPA's implementing regulations. Because the approach establishes loads on the basis of a representative flow regime, it inherently considers seasonal variations and critical conditions attributed to flow conditions. An underlying premise of the duration curve approach is correlation of water quality impairments to flow conditions. The duration curve alone does not consider specific fate and transport mechanisms, which may vary depending on watershed or pollutant characteristics.

6.2 Modeling Approach for Dissolved Oxygen

The QUAL2K model is used to support TMDL development for streams impaired due to dissolved oxygen. Historical data are used to model stream water quality for GB-16, new data were collected in 2016 for GBK-14 and GBKA to support model development.

QUAL2K simulates up to 15 water quality constituents in branching stream systems. A stream reach is divided into a number of computational elements, and for each computational element, a hydrologic balance in terms of stream flow (e.g., m₃/s), a heat balance in terms of temperature (e.g., degrees C), and a material balance in terms of concentration (e.g., mg/l) are written. Both advective and dispersive transport processes are considered in the material balance. Mass is gained or lost from the computational element by transport processes, wastewater discharges, and withdrawals. Mass can also be gained or lost by internal processes such as release of mass from benthic sources or biological transformations.

QUAL2K simulates changes in flow conditions along the stream by computing a series of steady-state water surface profiles. The calculated stream-flow rate, velocity, cross-sectional area, and water depth serve as a basis for determining the heat and mass fluxes into and out of each computational element due to flow. Mass balance determines the concentrations of conservative minerals, coliform bacteria, and nonconservative constituents at each computational element. In addition to material fluxes, major processes included in the mass balance are transformation of nutrients, algal production, benthic and carbonaceous demand, atmospheric reaeration, and the effect of these processes on the dissolved oxygen balance. QUAL2K uses chlorophyll a as the indicator of planktonic algae biomass. The nitrogen cycle is divided into four compartments: organic nitrogen, ammonia nitrogen, nitrite nitrogen, and nitrate nitrogen. In a similar manner, the phosphorus cycle is modeled by using two compartments. The primary internal sink of dissolved oxygen in the model is biochemical oxygen demand (BOD). The major sources of dissolved oxygen are algal photosynthesis and atmospheric reaeration.

The model is applicable to dendritic streams that are well mixed. It assumes that the major transport mechanisms, advection and dispersion, are significant only along the main direction of flow (the longitudinal axis of the stream or canal). It allows for multiple waste discharges, withdrawals, tributary flows, and incremental inflow and outflow.

Hydraulically, QUAL2K is limited to the simulation of time periods during which both the stream flow in river basins and input waste loads are essentially constant. QUAL2K can operate as either a steady-state or a quasidynamic model, making it a very helpful water quality planning tool. When operated as a steady-state model, it can be used to study the impact of waste loads (magnitude, quality, and location) on instream water quality. By operating the model dynamically, the user can study the effects of diurnal variations in meteorological data on water quality (primarily dissolved oxygen and temperature) and also can study diurnal dissolved oxygen variations due to algal growth and respiration. However, the effects of dynamic forcing functions, such as headwater flows or point loads, cannot be modeled in QUAL2K.

QUAL2K is an appropriate choice for certain types of dissolved oxygen TMDLs that can be implemented at a moderate level of effort. Use of the QUAL2K models in TMDLs is most appropriate when (1) full vertical mixing can be assumed, and (2) water quality excursions are associated with identifiable critical flow conditions. Because the model does not simulate dynamically varying flows, its use is limited to evaluating responses to one or more specific flow conditions including the critical flow.

The dissolved oxygen deficit (DOD) is used to express the loading capacity and allocations for streams without point sources (i.e., Spring Brook GBKA and West Branch DuPage River GBK-14). DOD is a measure of the impacts of all DO-depleting sources and has units of mg-DO/L. The loading capacity for DO is the difference between DO_{sat} (a function of temperature) and the water quality standard, expressed as DOD. A high DOD indicates the presence of significant causes of DO depletion. DOD may also be negative, if DO concentration exceeds DO_{sat} (as often happens during periods of active photosynthesis in dense algal mats), which indicates supersaturated conditions. The ideal situation is for DOD to be zero or close to zero. This would indicate the smallest deviation from the natural equilibrium level of DO_{sat}. Because DO_{sat} varies as a function of temperature, DOD also varies with temperature (Figure 33).

Figure 33. Assimilative capacity as a function of DO saturation.

The DOD load that meets the DO standard can be calculated for a steady-state condition using QUAL2K. Note that QUAL2K cannot be used directly to identify precise DOD impacts of oxygen-demanding sources such as CBOD, NBOD, or algal respiration, but impacts of SOD and headwater DO which dominate the system can be estimated from model output. Like DO, DOD can be converted to a load by multiplying by flow:

$$DOD\left[\frac{kg}{d}\right] = (DO_{sat} - DO)[mg/L] \times Q[cfs] \times 2.447[conversion factor]$$

The conversion factor is the result of the following unit conversions: seconds to days, cubic feet to liters, and milligrams to kilograms.

6.3 Allocations

A TMDL is the total amount of a pollutant that can be assimilated by the receiving water while still achieving water quality standards. TMDLs are composed of the sum of individual wasteload allocations (WLAs) for regulated sources and load allocations (LAs) for unregulated sources and natural background levels. In addition, the TMDL must include a margin of safety (MOS), either implicitly or explicitly, that accounts for the uncertainty in the relationship between pollutant loads and the quality of the receiving waterbody. A reserve capacity (RC) can be included to account for future growth. Conceptually, this is defined by the equation:

$$\mathsf{TMDL} = \sum \mathsf{WLAs} + \sum \mathsf{LAs} + \mathsf{MOS} + \mathsf{RC}$$

Section 7.0 presents the allowable loads and associated allocations for each of the impaired waterbodies in the watershed.

Existing fecal coliform loads are based on the 90th percentile observed loads within each flow regime during the standard window of May–October. Observed loads are calculated by multiplying the observed water quality sample concentration by the average daily flow on the day the sample was collected. The fecal coliform TMDLs are based on compliance with both the single sample maximum standard (400 cfu/100 mL) and the geomean standard (200 cfu/100 mL). For the single sample maximum standard, load reductions are based on the existing load and the median allowable load in each flow regime. It was not possible to calculate reductions relative to the geomean standard due to limited monitoring data.

For the chloride TMDL on GB-11, existing loads are based on the maximum observed load within each flow regime. Load reductions are calculated using the existing load and the median allowable load in each flow regime. Existing loads and reductions needed to meet the dissolved oxygen standard in GB-16 are based on Qual2K modeling. Impairments for chloride and dissolved oxygen in the Lower DuPage River watershed (GB-11 and GB-16, respectively) include a boundary condition set at the confluence of the East Branch and West Branch DuPage Rivers. The boundary condition assumes compliance with both chloride and dissolved oxygen standards and is used to represent the outcome of TMDLs approved in 2004 for these rivers.

6.3.1 Wasteload Allocation

Numerous known NPDES facilities are within the watershed with the potential to discharge pollutants. Wasteload allocations (WLAs) are assigned to each permitted point source that contributes to an impairment. For NPDES facilities discharging to fecal coliform impairments, Illinois EPA assumes that facilities with a fecal coliform limit are considered a source of fecal coliform and therefore these facilities are provided a WLA (Table 18). Stonewall Utility Company (IL0052817) does not have a current permit limit but was given a WLA based on a fecal coliform monitoring requirement. A full list of fecal coliform WLAs is provided in Appendix F. Illinois EPA assumes that WWTPs are contributing to chloride and dissolved oxygen impairments and are therefore provided WLAs.

Fecal coliform WLAs are based on NPDES permit information and on meeting both the geometric mean fecal coliform water quality standard and the instantaneous water quality standard. Facility design flows are used to calculate a daily load and serve as the WLA for NPDES permitted facilities. Permitted maximum design flows are used for WLAs under high flow conditions and permitted average design flows are used for moist to low flows. The WLA for Stonewall Utility Company (IL0052817) applies at the end of the disinfection exemption. Facilities with disinfection exemptions may be required to provide Illinois EPA with updated information to demonstrate compliance with these requirements, and facilities directly discharging into a fecal-impaired segment may have their year-round disinfection exemption re-evaluated through future NPDES permitting actions.

There are eight facilities with permitted combined sewer overflows (CSOs) in the watershed (Table 19). WLAs for CSOs are provided during high flow conditions only. The WLAs for non-MWRD's CSOs were calculated to be equal to the maximum flow associated with a CSO event during the time period 2013–2015, as reported in Illinois EPA's discharge monitoring reports (DMRs) or as provided by the permitted entity, multiplied by the water quality standard for fecal coliform. When no flow information was available, a WLA equal to zero was assigned. A categorical WLA was provided to the CSOs that are a part of MWRD's Tunnel and Reservoir Plan (TARP) System, which conveys combined sewer flow through tunnels to storage reservoirs. After an event is over, the water in the reservoirs is pumped to a water reclamation plant, treated, and discharged to surface waters. MWRD's WLA for each impairment is a sum of the maximum estimated volume associated with a CSO event at each of the relevant TARP structures, based on 2013–2015 data provided in MWRD's quarterly reports to Illinois EPA. CSO WLAs apply when the permitted facility is in compliance with their approved Long-Term Control Plans (LTCPs), which will stipulate no more than four overflows per year and that discharge will not cause or contribute to water quality exceedances.

Several NPDES facilities in the watershed also have permitted excess flows. The excess flows at these facilities have primary treatment and disinfection with a fecal coliform limit and occur when the primary treatment facility reaches the maximum flow capacity. Discharges during wet weather events need to be in compliance with all applicable permit requirements. Due to the increased assimilative capacity of the receiving waters during extreme wet weather, daily load allocations are not appropriate. Fecal coliform concentration limits must be met for all flows at all times, including during extreme wet weather events.

Chloride WLAs are based on NPDES permit information and meeting the 500 mg/L general use water quality standard in the effluent. Facility design flows are used to calculate a daily load which serve as the WLA. Permitted maximum design flows are used for WLAs under high flow conditions and permitted average design flows are used for moist to low flows. NPDES permitted facilities that discharge downstream of the boundary condition and are provided a chloride WLA include: Bolingbrook WRF #3 (IL0069744), Joliet Aux Sable WWTP

(IL0076414), Naperville Spring-Brook WRC (IL0034061) and Plainfield North STP (IL0074373). A full list of chloride WLAs is provided in Appendix F.

WLAs for facilities discharging directly to segment GB-16 that is impaired for low dissolved oxygen include Naperville WWTP (IL0034061), Bolingbrook WWTP (IL0069744), and Plainfield WWTP (IL0074373). A boundary condition is set at the upstream boundary of GB-16, as described in Appendix F. WLAs are assigned based on permitted flow conditions and concentrations needed to meet dissolved oxygen conditions in the river, also described in Appendix F.

There are numerous regulated MS4s in the watershed (Appendix J). WLAs for NPDES-permitted MS4s, which do not have numeric effluent limitations, are expressed as a portion of the loading capacity based on area within the watershed. For the fecal coliform TMDLs, a categorical WLA was established for MS4s based on the proportion of the non-agricultural land covers in the impairment watershed (Table 23). For the GB-11 chloride impairment, a categorical WLA was established for the GB-11 watershed area downstream of the boundary condition. A similar categorical WLA was established for all MS4s with the exception of the Illinois Department of Transportation (ILDOT). ILDOT provided road right-of-way widths that were used to calculate an individual WLA based on the proportion of ILDOT road area. The proportion of ILDOT road area in the GB-11 watershed downstream of the boundary condition is 2% and the proportion of non-agricultural land covers is 75%.

		Land Cover Summary (2011 NLCD)						
Waterbody ID	Waterbody Name	Developed	Agriculture	Wetlands/ Water	Barren/Forest/ Shrub/ Herbaceous			
IL_GB-11 (Fecal coliform) ^a	DuPage River	78%	11%	3%	8%			
IL_GB-11 (Chloride) ^b	DuPage River	67%	23%	3%	5%			
IL_GB-16	DuPage River	79%	9%	3%	9%

IL_GL-10	Salt Creek	87%	2%	4%	7%			
IL_GL-19	Salt Creek	89%	3%	4%	4%			
IL_GLA-02	Addison Creek	98%	0%	1%	1%			

a. Includes all watershed area draining to this segment, including the East Branch and West Branch DuPage Rivers.b. Includes only that portion of the watershed downstream of the confluence of the East Branch and West Branch DuPage Rivers. The remaining upstream portion of the watershed is addressed by a boundary condition for chloride.

6.3.2 Margin of Safety

The CWA requires that a TMDL include a margin of safety (MOS) to account for uncertainties in the relationship between pollutants loads and receiving water quality. U.S. EPA guidance explains that the MOS may be implicit

(i.e., incorporated into the TMDL through conservative assumptions in the analysis) or explicit (i.e., expressed in the TMDL as loadings set aside for the MOS). A 10% explicit MOS has been applied as part of this TMDL for fecal coliform and chloride. A moderate MOS was specified because the use of the load duration curves is expected to provide accurate information on the loading capacity of the stream, but this estimate of the loading capacity may be subject to potential error associated with the method used to estimate flows within the watershed. The MOS for fecal coliform is also implicit because the load duration analysis does not address die-off of pathogens. A MOS was also added to the dissolved oxygen TMDLs by adjusting the standard to be 10% higher. For example, the minimum allowable dissolved oxygen concentration is 4.0 mg/l in August for GB-16; the MOS was incorporated by setting the minimum dissolved oxygen target to 4.4 mg/L for August.

6.3.3 Reserve Capacity

Reserve capacity (RC) is provided to those watersheds that are expected to further develop. No reserve capacity is set aside at this time. For fecal coliform, any new or expanded discharges will be required to comply with permit limits. As long as the facility is meeting the single sample maximum and geomean standards, any new flow and associated load will be in compliance with the TMDL.

No specific reserve capacity is provided for chloride, although chloride is expected to increase as development takes place in the watershed. The current load allocation that accounts for loading from non-MS4 areas is assigned the same chloride loading rate per acre as the current MS4 areas. As non-MS4 areas are developed, the LA should transfer to WLA.

6.3.4 Load Allocation

Load allocations represent the portion of the allowable load that is reserved for nonpoint sources and natural background conditions. The load allocations are based on subtracting the allocations for WLAs and MOS from allowable loads.

6.4 Critical Conditions and Seasonality

The CWA and USEPA's regulations require that TMDLs include a component to address seasonal variations and critical conditions for stream flow, loading, and water quality parameters. Critical conditions are the period when the greatest reductions in loading are required. The loading capacity is set to achieve desired water quality standards which apply during the entire year. Use of load duration curves, however, analyzes in-stream concentrations on a daily basis over the entire range of observable flows. Therefore, the critical condition for load duration TMDLs is established by hydrologic category, defined as the greatest reduction needed to meet WQS among all hydrologic categories. Dissolved oxygen impairments are modeled during critical conditions, and therefore the loading capacity and targets derived from that modeling directly apply to critical conditions.

7.0 Total Maximum Daily Loads

TMDLs are provided for those impairments included in Table 21. The section is organized by impaired stream.

7.1 DuPage River (IL_GB-11)

7.1.1 Fecal Coliform TMDL

A fecal coliform bacteria TMDL has been developed for the DuPage River segment GB-11. Figure 34 presents the fecal coliform load duration curve and Table 24 and Table 25 summarize the TMDL and required reductions for both the single sample maximum standard and the geomean standard, respectively. Pollutant reductions are needed for all flow conditions, except under dry flows. Table 26 summarizes the individual wasteload allocations.

				Flow Zones		
тмі	DL Parameter	Flows Conditions Flows Conditions		Low Flows		
			Fecal Colif	orm Load (billi	ion cfu/day)	
	CSOs ^c	372	-	-	-	-
Wasteload Allocation	NPDES-permitted facilities	4,825	2,134	2,134	b	b
	MS4 ^d	5,641	1,931	339	b	b
Load Allocation		769	263	46	b	b
MOS		1,290	481	280	183	126
Loading Capacit	y	12,897	4,809	2,799	1,830	1,260
Existing Load		34,398	12,109	5,271	1,481	1,764
Load Reduction ^a		63%	60%	47%	0%	29%

a. TMDL reduction is based on the observed 90th percentile load in each flow regime.

b. The permitted wastewater treatment facility design flows exceed the long-term monitored stream flow in the dry and low flow zones. NPDES-permitted facilities can discharge under these flow conditions if meeting permit conditions. To account for these unique situations only, the WLAs and LA are expressed as an equation rather than an absolute number: Wasteload Allocation or Load Allocation = (flow contribution from a given source) x (400 counts per 100 mL). The allowable concentration is based on water quality standards. c. CSO events are assumed to occur no more than 4 times per year.

d. The MS4 WLA is categorical, see section 6.3.1 for description.

Table 25. Fecal coliform TMDL summary (geomean standard; DuPage River at GB-11)

				Flow Zones		
ТМІ	DL Parameter	HighMoistMid-RangeDryFlowsConditionsFlowsConditions		-	Low Flows	
			Fecal Colif	orm Load (billi	on cfu/day)	
	CSOs °	186	-	-	-	-

d. Maximum CSO volumes from 2013-2015 DMRs.

c. CSOs are only allowed to discharge 4 times per year at this level.

7.2.2 Dissolved Oxygen TMDL

CBOD₅, total phosphorus, and ammonia TMDLs were developed to address low dissolved oxygen in GB-16 (Table 34). A calibrated QUAL2K model was developed to simulate critical summer conditions and derive the TMDLs (see Appendix E). The calibrated model simulated conditions on 8/1/2006 and a series of scenarios were then evaluated (Table 32 and Figure 37).

Table 32. Model scenarios

Scenario	Scenario Description
1	Critical conditions:
	 Headwater flow decreased to 1.699 cms (60 cfs)
	Headwater DO decreased to 6 mg/L
	 Point source flows and water quality changed to permit limits (see Table 33)
2	Scenario 1 with the following modifications to meet water quality standards with margin of safety:
	SOD rate reduced to 2.04 g/m ² /d
	 Point source minimum DO increased to 6.5 mg/L
	 Bolingbrook and Plainfield WWTPs CBOD₅ decreased to 10 mg/L
	 Headwater TP decreased to 1 mg/L
	 Naperville WWTP CBOD₅ decreased to 7.5 mg/L
	 SOD coverage decreased by half to 7.5%
3	Scenario 1 with the following modifications to meet water quality standards with margin of safety:
	 SOD rate to 2.04 g/m²/d
	 Point Source DO minimum increased to 6.5 mg/L
	 Bolingbrook and Plainfield WWTPs CBOD₅ decreased to 10 mg/L
	 Headwater TP decreased to 1 mg/L
	Naperville WWTP CBOD₅ unchanged
	SOD coverage decreased to 5.0%

Table 33. NPDES point s	source permit monthl	ly average concentration limits

Ammonia (mg/L)	1.4	1.5	1.5
Total Phosphorus (mg/L)	1	1	1
DO (mg/L)	6.0	6.0	6.0

Figure 37. Model scenarios compared to observed data and calibrated model.

In GB-16, point sources discharging under their current permit limits are contributing to low DO conditions. In addition, the flow and chemistry of water flowing into this segment and SOD are also contributing to low DO conditions during critical conditions. Two allocation scenarios (Scenario 2 and Scenario 3) are provided in Table 34. For each of these scenarios, implementation targets are also provided that are required in combination with the pollutant load allocations to meet DO standards in GB-16.

A scenario that does not impact permit limits was not modeled as part of TMDL development, TMDL development requires an evaluation of the current permit limits, and assumes that facilities discharge at those limits during critical conditions. Additional scenarios will also likely meet the minimum DO conditions and Illinois EPA will consider alternative scenarios or solutions to meet the DO water quality standards. One such scenario could focus on the development and implementation of watershed-wide practices to reduce SOD inputs, increase rates of in-stream aeration, and decrease CBOD₅ inputs from nonpoint sources. As part of this alternative, stakeholders and point source dischargers would continue to implement their current adaptive management approaches. Stakeholders would collaborate to identify and implement solutions to meet to identify and implement specific actions that reduce ambient SOD and SOD inputs, increase CBOD₅ assimilation and reduce CBOD₅ inputs, and improve aquatic ecology. Alternative scenarios, best management practices, and other waterway modifications would need to be itemized by the watershed group for inclusion as action items in the member agencies permits. This type of scenario was developed based on language provided by Illinois EPA's Permit Division¹ (A. Keller, personal communications).

¹ From Al Keller, IEPA, 4/28/2017: "The Agency has encouraged watershed groups to form to develop solutions to address impairments in streams and to benefit multiple communities or districts. The Agency has included specific action items from watershed groups in the group member's NPDES permits in order to address stream impairments. Alternative scenarios, BMPs, and other waterway modifications need to be itemized by the watershed group for inclusion as action items in the

Additional monitoring and further refinement of the QUAL2K model is recommended.

Illinois EPA expects that the USEPA will approve the most restrictive set of allocations as part of the formal approval process, however, Illinois EPA also expects that USEPA will consider the potential for other scenarios that could be used to meet the TMDLs as long as the allocations are consistent between the permits and the TMDLs. This approach allows flexibility on the part of Illinois EPA to consider alternate approaches to implementing the TMDLs.

permits. Please note that the TMDL would still need to have a final solution approved, such as lower effluent limits and a WLA, for meeting the DO standard. The Agency cannot guarantee to substitute using alternative solutions for 10 or 20 years but will review the progress made during each permit cycle. New regulations or new directives by USEPA will need to be addressed in each permit cycle. WLAs or lower effluent limits from an approved TMDL may need to be included in subsequent permits in addition to alternative solutions if the WQ standards are not met".

7.3 West Branch DuPage River (IL_GBK-05)

7.3.1 Fecal Coliform TMDL

A fecal coliform bacteria TMDL has been developed for the West Branch DuPage River segment GBK-05. Figure 38 presents the fecal coliform load duration curve and Table 35 and Table 36 summarize the TMDL and required reductions for both the single sample maximum standard and the geomean standard, respectively. Pollutant reductions are needed for all flow conditions. Table 37 summarizes the individual WLAs.

Figure 38. Fecal coliform load duration curve, West Branch DuPage River at GBK-05.

Table 35. Fecal coliform	TMDL summary (single sample maximum standard; West Branch DuPage River
at GBK-05)	

		Flow Zones						
ТМС	DL Parameter	High Flows	Moist Conditions	Mid-Range Flows	Dry Conditions	Low Flows		
			Fecal Coliform Load (billion cfu/day)					
Wasteload Allocation	NPDES-permitted facilities	1,405	642	642	b	b

Table 42. Fecal coliform TMDL summary (geomean standard; West Branch DuPage River at GBK-14)

a. The MS4 WLA is categorical, see section 6.3.1 for description.

b. Insufficient data to calculate reduction based on the geomean standard.

7.5.2 Dissolved Oxygen

A dissolved oxygen deficit (DOD) TMDL was developed to address low dissolved oxygen in GBK-14. DOD is a measure of the impacts of all DO-depleting sources and also has units of mg-DO/L. The loading capacity for DO is the difference between DO_{sat} (a function of temperature) and the water quality standard of 5.0 mg/L, expressed as DOD. An example TMDL is provided in Table 43 and is applicable to the following critical conditions:

- Flow of 1.33 cfs
- Water temperature of 19.4 °C
- DO_{sat} of 8.96 mg/l (derived from QUAL2K modeling for critical conditions)

A DOD TMDL can be calculated for any other combination of flow and water temperature using the following equation:

$$DOD\left[\frac{kg}{d}\right] = (DO_{sat} - DO) [mg/L] x Q [cfs] x 2.447 [conversion factor]$$

A calibrated QUAL2K model was developed to simulate critical summer conditions in GBK-14 and determine the implementation activities needed to meet the DOD TMDL (see Appendix E). The low DO in GBK-14 is estimated to be caused be a combination of low reaeration and the presence of SOD, along with exacerbation of existing conditions due to very low flow (only several inches of stream depth).

TMDL Parameter	DOD (kg/day)	DOD (Ibs/day)				
Wasteload Allocation: MS4 ^a	0 ^b	0 ^b				
Load Allocation	11	24				
MOS °	implicit	implicit				
Loading Capacity (kg/day) ^d	11	24				
Existing Load (kg/day)	19	42				
Load Reduction	42	42%				

Table 43. Dissolved oxygen demand	I TMDL summary (GBK-14)
-----------------------------------	-------------------------

a. The MS4 WLA is categorical, see section 6.3.1 for description.

b. This TMDL is provided for critical conditions occurring during low flow summer months; CSO and stormwater discharges are not anticipated at this time.

c. A 10% MOS was applied to the standard during modeling; see Appendix E.

d. TMDL is provided for critical conditions: Flow = 1.33 cfs; Water temperature = 19.4 °C; DO_{sat} = 8.96 mg/l. TMDLs can be determined for any combination of flow and water temperature using the following equation:

 $DOD\left[\frac{kg}{d}\right] = (DO_{sat} - DO) [mg/L] \times Q [cfs] \times 2.447 [conversion factor]$

In addition to the DOD loading capacity and allocations, implementation targets are provided that would lead to compliance with the TMDL. Any of these activities alone will result in meeting the DO standard, they can also be used in combination:

- Increased reaeration rate (increased from 1.1 to 2.1 per day)
- Reduced SOD (decreased by half from 2.04 to 1.02 gO₂/m²/d)
- Combination of increased reaeration (increased 35%) and reduced SOD (decreased 35%)
- Increased streamflow (increased headwater streamflow from 0.038 to 0.110 m³/s)

7.6 Spring Brook (IL_GBKA)

7.6.1 Fecal Coliform TMDL

A fecal coliform bacteria TMDL has been developed for the Spring Brook segment GBKA. Figure 41 presents the fecal coliform load duration curve and Table 44 and Table 45 summarize the TMDL and required reductions for both the single sample maximum standard and the geomean standard, respectively. Pollutant reductions are needed for all flow conditions.

Figure 41. Fecal coliform load duration curve, Spring Brook at GBKA.

	Flow Zones				
TMDL Parameter	High	Moist	Mid-Range	Dry	Low Flows
	Flows	Conditions	Flows	Conditions	
	Fecal Coliform Load (billion cfu/day)

Loading Capacity	112	52	32	23	16
Existing Load	7,380	1,737	809	100	117
Load Reduction ^b	Not calculated				

a. The MS4 WLA is categorical and accounts for 100% of the watershed, therefore the LA=0. See section 6.3.1 for description.

b. Insufficient data to calculate reduction based on the geomean standard.

7.6.2 Dissolved Oxygen

A dissolved oxygen deficit (DOD) TMDL was developed to address low dissolved oxygen in Spring Brook. DOD is a measure of the impacts of all DO-depleting sources and also has units of mg-DO/L. The loading capacity for DO is the difference between DO_{sat} (a function of temperature) and the water quality standard of 5.0 mg/L, expressed as DOD. An example TMDL is provided in Table 46 and is applicable to the following critical conditions:

- Flow of 4.3 cfs
- Water temperature of 22.26 °C
- DOsat of 8.76 mg/l (derived from QUAL2K modeling for critical conditions)

A DOD TMDL can be calculated for any other combination of flow and water temperature using the following equation:

$$DOD\left[\frac{kg}{d}\right] = (DO_{sat} - DO) [mg/L] x Q [cfs] x 2.447 [conversion factor]$$

A calibrated QUAL2K model was developed to simulate critical summer conditions in Spring Brook and derive the DOD TMDL (see Appendix E). In the lowest part of the stream segment, SOD accounts for 36% of the DOD and inflow from upstream accounts for the remaining 64% of DOD. SOD and lack of reaeration were identified as the primary drivers of low dissolved oxygen in this impaired stream.

TMDL Parameter	DOD (kg/day)	DOD (lbs/day)	
Wasteload Allocation: MS4 ^a	0 ^b	0 ^b	
Load Allocation	39	86	
MOS °	implicit	implicit	
Loading Capacity ^d	39	86	
Existing Load	59	130	
Load Reduction	34%		

a. The MS4 WLA is categorical, see section 6.3.1 for description.

b. This TMDL is provided for critical conditions occurring during low flow summer months; stormwater discharges are not anticipated at this time.

c. A 10% MOS was applied to the standard during modeling; see Appendix E.

d. TMDL is provided for critical conditions: Flow = 4.3 cfs; Water temperature = 22.26 °C; DO_{sat} = 8.76 mg/l. TMDLs can be determined for any combination of flow and water temperature using the following equation:

$$DOD\left[\frac{kg}{d}\right] = (DO_{sat} - DO) [mg/L] \times Q [cfs] \times 2.447 [conversion factor]$$

In addition to the DOD loading capacity and allocations, implementation targets are provided that would lead to compliance with the TMDL:

 Increased reaeration (0.4 /d) and decreased SOD coverage and rate (50%, 1.05 gO2/m2/d) in the lower reach

It is also possible to achieve the DO criteria and the maximum allowable DOD by exclusively decreasing SOD in the lower reach or exclusively increased reaeration in the lower reach.

7.7 Spring Brook (IL_GBKA-01)

7.7.1 Fecal Coliform TMDL

A fecal coliform bacteria TMDL has been developed for the Spring Brook segment GBKA-01. Figure 42 presents the fecal coliform load duration curve and Table 47 and Table 48 summarize the TMDL and required reductions for both the single sample maximum standard and the geomean standard, respectively. Pollutant reductions are needed for all flow conditions.

Figure 42. Fecal coliform load duration curve, Spring Brook at GBKA-01.

		Flow Zones				
TMDL Parameter		High Flows	Moist Conditions	Mid-Range Flows	Dry Conditions	Low Flows
			Fecal Colif	orm Load (billi	on cfu/day)	
Wasteload Allocation	NPDES-permitted facility: IL0031739 (Wheaton S.D.) ^a	289 (at DMF)	135 (at DAF)	b	b	b
	MS4 ^c	62	27	b	b	b
Load Allocation	Load Allocation		1	b	b	b
MOS		39	18	11	8	6
Loading Capacity		391	181	110	79	55
Existing Load		5,777	1,610	211	103	148
Load Reduction ^d		93%	89%	48%	23%	63%

a. DMF = 19.1 MGD, DAF = 8.9 MGD

b. The permitted wastewater treatment facility design flows exceed the long-term monitored stream flow in the dry and low flow zones. NPDES-permitted facilities can discharge under these flow conditions if meeting permit conditions. To account for these unique situations only, the WLAs and LA are expressed as an equation rather than an absolute number: Wasteload Allocation or Load Allocation = (flow contribution from a given source) x (400 counts per 100 mL). The allowable concentration is based on water quality standards. c. The MS4 WLA is categorical, see section 6.3.1 for description.

d. TMDL reduction is based on the observed 90th percentile load in each flow regime.

a. NPDES-permitted facility with excess flow outfall – excess flows not included in WLAs. b. CSOs are only allowed to discharge 4 times per year at this level. c. Maximum CSO volumes from 2013-2015 DMRs. d. MWRD-permitted facilities are combined into one categorical WLA.

7.12 Addison Creek (IL_GLA-02)

7.12.1 Fecal Coliform TMDL

A fecal coliform bacteria TMDL has been developed for Addison Creek segment GLA-02. Figure 46 presents the fecal coliform load duration curve and Table 60 and Table 61 summarize the TMDL and required reductions for both the single sample maximum standard and the geomean standard, respectively. Pollutant reductions are needed for all flow conditions.

Figure 47. Fecal coliform load duration curve, Addison Creek at GLA-02.

				Flow Zones		
TMDL Parameter		High Flows	Moist Conditions	Mid-Range Flows	Dry Conditions	Low Flows
			Fecal Colif	orm Load (billi	on cfu/day)	
	CSO: IL0020853 (MWRDGC STICKNEY WRP CSOS – 150) ^a	b	-	-	-	-

Existing Load		-	18,705	6,727	2,407	1,377
Load Reduction ^f		-	98%	98%	97%	97%

Table 60. Fecal coliform TMDL summary (single sample maximum standard; Addison Creek at GLA-02)

a. CSO events are assumed to occur no more than 4 times per year.

b. Permitted CSO loads are estimated to be approximately 5,891 billion cfu/event. Permitted CSO facilities can discharge under high flow conditions if meeting permit conditions and long-term control plans.

c. DMF = 10 MGD, DAF = 4.7 MGD. NPDES-permitted facility with excess flow outfall – excess flows not included in WLA. d. The permitted wastewater treatment facility design flows exceed the long-term monitored stream flow in the dry and low flow zones. NPDES-permitted facilities can discharge under these flow conditions if meeting permit conditions. To account for these unique situations only, the WLAs and LA are expressed as an equation rather than an absolute number: Wasteload Allocation or Load Allocation = (flow contribution from a given source) x (400 counts per 100 mL). The allowable concentration is based on water quality standards. e. The MS4 WLA is categorical, see section 6.3.1 for description.

f. TMDL reduction is based on the observed 90th percentile load in each flow regime.

Table 61. Fecal coliform TMDL summary (geomean standard; Addison Creek at GLA-02)

TMDL Parameter		Flow Zones				
		High Flows	Moist Conditions	Mid-Range Flows	Dry Conditions	Low Flows
			Fecal Colif	orm Load (billi	on cfu/day)

a. CSO events are assumed to occur no more than 4 times per year.

b. Permitted CSO loads are estimated to be approximately 2,945 billion cfu/event. Permitted CSO facilities can discharge under high flow conditions if meeting permit conditions and long-term control plans.

c. DMF = 10 MGD, DAF = 4.7 MGD. NPDES-permitted facility with excess flow outfall - excess flows not included in WLA.

d. The permitted wastewater treatment facility design flows exceed the long-term monitored stream flow in the dry and low flow zones. NPDES-permitted facilities can discharge under these flow conditions if meeting permit conditions. To account for these unique situations only, the WLAs and LA are expressed as an equation rather than an absolute number: Wasteload Allocation or Load Allocation = (flow contribution from a given source) x (200 counts per 100 mL). The allowable concentration is based on water quality standards. e. The MS4 WLA is categorical, see section 6.3.1 for description.

f. Insufficient data to calculate reduction based on the geomean standard.

8.0 Implementation Plan and Reasonable Assurance

The implementation plan identifies activities that stakeholders could consider to reduce pollutant loads and improve the conditions of the impaired waterbody segments in the watershed, and provides reasonable assurance that required load reductions will be achieved. These implementation activities will help to achieve pollutant load reductions and attain water quality standards and also result in a cleaner, healthier watershed for the people who depend on the resources of the watershed for their livelihood now and in the future.

8.1 Introduction

This implementation plan is a framework that watershed stakeholders may use to guide implementation of best management practices (BMPs) to address TMDLs in the DuPage River and Salt Creek watersheds. This framework is flexible and incorporates adaptive management to allow watershed stakeholders to adjust the implementation plan to align with their priorities and limitations. This flexibility is necessary because the implementation of nonpoint source controls is voluntary. For example, an implementation plan that specifies a parking lot location for permeable pavement installation would be of little use to watershed stakeholders if the property owners at the specified locations are unwilling or unable to implement. Adaptive management is also necessary because factors unique to specific localities may yield better or worse results for a certain BMP (or suite of BMPs) and the implementation plan will need to be modified to account for such results.

An important factor for implementation of the recommended BMPs is access to technical and financial resources. One potential source of funding is the Clean Water Act Section 319 Nonpoint Source Management grants. Section 319 grant funding supports implementation activities including technical and financial assistance, education, training, demonstration projects, and monitoring to assess the success of nonpoint source implementation projects. To be eligible for these funds, watershed management plans must address nine elements identified by U.S. EPA (2008, revised 2014) as critical for achieving improvements in water quality. These nine elements include:

- Identification of causes of impairment and pollutant sources or groups of similar sources that need to be controlled to achieve load reductions estimated within the plan
- Estimate of the load reductions expected from management measures
- Description of the nonpoint source management measures that will need to be implemented to achieve load reductions estimated in element 2; and identification of critical areas
- Estimate of the amounts of technical and financial assistance needed, associated costs, and the sources and authorities (e.g., ordinances) that will be relied upon to implement the plan
- An information and public education component; early and continued encouragement of public involvement in the design and implementation of the plan
- Implementation schedule
- A description of interim, measurable milestones for determining whether nonpoint source management measures or other control actions are being implemented
- Criteria to measure success and reevaluate the plan
- Monitoring component to evaluate the effectiveness of the implementation efforts over time

Although 319 plans are created to address nonpoint source pollution specifically, improvements to point source pollution control may also have great impacts on ambient water quality in the watershed. Due to the urban nature of the watershed as well as the active work of many point source facilities in water quality improvements in the area, the implementation plan also addresses point sources.

The DuPage River and Salt Creek watershed TMDLs, including this implementation plan, is considered a watershed plan that meets U.S. EPA's nine elements. Table 62 illustrates which sections of the document contain information that fulfills U.S. EPA's nine elements.

Table 62. Comparison of TMDL Study and Implementation Plan to U.S. EPA's Nine Elements

8.1.1 Pollutants of Concern

This implementation plan addresses impairments (see Section 1.2) due to fecal coliform, chloride, and low dissolved oxygen. TMDLs have been developed to address these impairments and are provided in Section 7 (Figure 48 and Figure 49). Additional impairments in the watershed include nutrients and sediment (Figure 50). TMDLs are not provided for these impairments and needed reductions to meet water quality standards are unknown, however, activities to reduce nutrient and sediment loading are also included in this plan.

Needed fecal coliform pollutant reductions are summarized in Table 63. Note that pollutant load reductions for river and stream TMDLs are dependent upon flow regime and are provided for waters meeting the single sample maximum standard of 400 counts/100 ml (see Section 4 for a description of these standards). There were insufficient data to evaluate needed reductions to meet the geometric mean standard of 200 counts/100 ml.

Figure 48. Fecal Coliform TMDL stream segments within the DuPage River and Salt Creek watersheds.

Figure 49. Dissolved oxygen and chloride TMDL stream segments within the DuPage River and Salt Creek watersheds.

Additional TMDLs have been developed previously and are not addressed in this plan, see Section 2.2.

Figure 50. Phosphorus and sediment impaired streams (no TMDLs developed) within the DuPage River and Salt Creek watersheds.

GLA-02	Addison Creek	No data	98%	98%	97%	97%

Table 63. Fecal coliform reductions needed	I in watershed to meet the single sample maximum standard

In the case of chloride, TMDLs have been developed previously for portions of the West Branch DuPage River, East Branch DuPage River, and Salt Creek. A new TMDL has been developed for GB-11 as part of this study. This stream segment is located at the downstream end of the Lower DuPage River. Reductions in chloride in GB-11 range from 47-74% and are needed during both winter and non-winter seasons. Existing TMDLs were developed to address chloride in the East Branch and West Branch DuPage Rivers; implementation of the GB-11 TMDL relies on meeting water quality standards in these upstream reaches per their respective TMDLs which require a 33-35% reduction in chloride loading.

TMDLs that address low dissolved oxygen conditions have also been previously developed for portions of the East Branch DuPage River and Salt Creek. Three additional TMDLs that address low dissolved oxygen conditions were developed for this study: GB-16 (segment on Lower DuPage River), GBKA (Spring Brook, tributary to West Branch DuPage River), and GBK-14 (headwaters to West Branch DuPage River). Implementation targets have been provided for each of these impaired stream segments that include a mix of point source permit compliance or point source reductions along with reductions to nonpoint sources such as SOD.

In addition to the TMDL pollutants described above, other nonpoint sources of pollutants exist in the watershed resulting in sediment and nutrient loading. While no TMDLs are provided for these pollutants, nonpoint sources of these pollutants are important to overall watershed health and are addressed within this plan.

8.1.2 Planning Area

The DuPage River and Salt Creek watersheds are comprised of four main subwatersheds including the East Branch DuPage River, West Branch DuPage River, Lower DuPage River, and Salt Creek (Figure 51), however, the planning area for this document only covers the East Branch, West Branch and Lower DuPage rivers. An implementation planning effort is underway for Salt Creek by the Chicago Metropolitan Agency for Planning (CMAP). This plan is anticipated to be competed in 2018 and will address both the impaired waters in the Salt Creek watershed as well as other water quality concerns. In addition to the Salt Creek watershed planning effort, other smaller planning efforts have been completed or are underway (see Table 64). In these areas, the local watershed plans will take precedence. Portions of this implementation plan are divided into the main subwatersheds: East Branch, West Branch, and the Lower DuPage. This format allows analysis and recommendations at the appropriate scale for each subwatershed, highlights the unique characteristics of the subwatershed, and addresses the specific concerns and objectives of local stakeholders and organizations as described in existing plans.

Figure 51. DuPage River and Salt Creek subwatersheds.

East Branch DuPage River Watershed

The East Branch DuPage River subwatershed covers approximately 81 square miles in the east central portion of the DuPage River and Salt Creek watersheds (Figure 52). The headwaters begin in the Village of Bloomingdale and flow south until the confluence with the West Branch DuPage and start of the Lower DuPage River. The subwatershed lies mainly in DuPage County but includes portions of Will County in the south. Pollutants of concern include fecal coliform, nutrients, and sediment.

The watershed is highly urbanized and developed with many channelized streams. Land use is predominantly residential. Riparian buffers are generally in poor condition with little vegetation and tree cover (Midwest Biodiversity Institute 2014). During the summer-fall season, the mainstem is dominated by effluent discharge from communities' wastewater treatment plants (WWTPs) (Hey and Associates et al. 2015). The watershed contains several unique natural areas including the Morton Arboretum, a 1,700 acre property that contains more than 222,000 live plants and eight Illinois Natural Areas Inventory sites that include high quality natural community or restoration, suitable habitat for listed species, and nature preserves, reserves or landmarks. The Churchill Woods Dam was modified in 2011 by watershed partners (DuPage County Stormwater Management, Forest Preserve District of DuPage County, and DRSCW) and restoration activities took place in the impoundment footprint upstream of the dam in an effort to improve water quality and promote fish passage.

West Branch DuPage River

The West Branch DuPage River subwatershed covers 128 square miles in the northwestern portion of the DuPage River and Salt Creek watersheds (Figure 53). The West Branch DuPage River begins near Schaumburg flowing south until its confluence with the East Branch DuPage River and start of the Lower DuPage River between Naperville and Bolingbrook. The main stem of the West Branch DuPage River measures 34 miles in length and is fed by 10 major tributaries. Land use is predominantly residential and urban with some agricultural land use in the western portions of the watershed. The watershed lies mainly within DuPage County, but encompasses portions of Kane, Cook, and Will counties. Pollutants of concern include fecal coliform, nutrients, and sediment. In addition, low dissolved oxygen conditions are present in two headwater reaches. The subwatershed contains several Forest Preserves including two that border the mainstem: West Branch and Blackwell. In 2008, the McDowell Grove dam was removed through a NRCS funded project in an effort to improve water quality and fish passage. DuPage County Stormwater Management has conducted multiple water quality and flood control projects along the West Branch since 2005. These projects have resulted in the removal of the Warrenville Grove Dam, 13 acres of floodplain restoration, stabilization of 7,625 linear feet of streambank, restoration of more than 58 acres of wetland and riparian vegetation, amongst other improvements.

Lower DuPage River

The Lower DuPage River subwatershed covers 168 square miles in the southern most portion of the DuPage River and Salt Creek watersheds (Figure 54). The Lower DuPage River begins at the confluence of the East and West Branches of the DuPage River within the DuPage River Confluence Preserve and flows south until its confluence with the Des Plaines River. The watershed is unique as it includes portions of the Illinois and Michigan Canal, a manmade canal which connects the river system to Lake Michigan located at its confluence with the Des Plains River (The Conservation Foundation 2011). In addition, the Lower DuPage River contains the 829 acre Lake Renwick Nature Preserve and the Heron Rookery Nature Preserve that provide refuge for several species of bird including, herons, egrets, cormorants, bald eagles, American white pelicans and several other winter water fowl (Forest Preserve District of Will County).

The subwatershed mostly lies within Will County but also includes small portions of DuPage, Grundy, and Kendall counties. The watershed contains 166 miles of streams and eight major tributaries. Land use is predominantly residential with portions of agricultural and commercial land. Agricultural land use, however, is expected to decrease in the near future as development pressure increases, in some cases, up to 400% from 2000-2030 (see Section 3 of the TMDL). Pollutants of concern include fecal coliform, nutrients, sediment, and chloride. Low dissolved oxygen conditions are also present in one reach.

Figure 52. East Branch DuPage River subwatershed land use.

Figure 53. West Branch DuPage River subwatershed land use.

Figure 54. Lower DuPage River subwatershed land use.

8.1.3 Existing and On-Going Planning Efforts

Portions of the DuPage River and Salt Creek watersheds have been the subject of watershed planning efforts developed on smaller, HUC12 watershed scales. Existing watershed plans such as these provide important local and regional stakeholder knowledge in addition to reasonable assurance that water quality improvement work will continue in the DuPage River watershed. This implementation plan incorporates and builds upon the concerns, priorities, recommendations, and data from these past planning efforts. Elements from exiting plans were incorporated, as appropriate. Table 64 provides a summary of existing watershed plans in the watershed including planned BMPs and involved parties.

In addition to watershed plan development, the DRSCW has developed an Implementation Plan (DRSCW 2015) to guide implementation activities that will result in attainment of aquatic life uses. The DRSCW uses statistical techniques to evaluate the relationship between observed aquatic communities and possible stressors. Possible stressors include landscape scale stressors (such as road density and basin size), ambient chemistry (such as chloride and phosphorous concentrations) and physical (using sub components of the QHEI such as measures of buffer width and stream sinuosity). The Identification and Prioritization System or IPS uses these and other data to identify and prioritize restoration opportunities in an adaptive management framework. The IPS prioritizes projects based on their ability to:

- Address the most limiting stressors at a reach level
- Prioritize reaches for intervention
- Establish restoration endpoints
- Provide a level of confidence in the likelihood of success
- Have measurable outcomes

The highest priority projects have already been placed within the permit special conditions (see Table 69), and additional projects have also been identified (see Section 8.5).

8.2 Nonpoint Source Assessment

Nonpoint sources of pollutants in the watershed are primarily related to runoff from agricultural land uses. However, in order to more fully assess the impacts of runoff in the watershed, all land covers were evaluated. The *Spreadsheet Tool for the Estimation of Pollutant Load* (STEPL) model is used to quantify watershed loadings in the East Branch DuPage River, West Branch DuPage River, and Lower DuPage River watersheds. STEPL modeling is being conducted by CMAP for the Salt Creek watershed and nonpoint sources for the Salt Creek watershed will be described in CMAP's Salt Creek Watershed Plan when completed. STEPL provides a simplified simulation of precipitation-driven runoff and sediment and nutrient delivery. STEPL has been used extensively in U.S. EPA Region 5 for watershed plan development and in support of watershed studies.

Model catchments were developed using existing catchment delineations provided by DuPage and Will counties and range from approximately 2,000 to 14,000 acres. Land cover data for the STEPL analysis were provided by CMAP. Appendix H includes a summary of CMAP land use classifications as used in the STEPL model. Existing BMPs and point sources are not included in the STEPL model setup. Annual pollutant loads of phosphorus, sediment, and BOD were calculated; results are provided below by subwatershed and in Appendix I.

At the time of this work, STEPL did not estimate fecal coliform nor chloride loading and reductions, therefore a qualitative approach was used to identify potential sources for each pollutant. For the purposes of this implementation plan, developed land cover is used as an indicator of both chloride and fecal coliform due to its imperviousness nature and likely presence of storms sewers.

East Branch DuPage River Subwatershed

The East Branch DuPage River watershed is heavily urbanized and urban sources contribute the vast majority of pollutants to the subwatershed. Cropland and other undeveloped land uses contribute less than 1% to phosphorus and BOD loading in the watershed and less than 3% of the total sediment loading. Additionally, as part of implementation development, a coarse analysis using air photos was conducted to identify potential areas of erosion; none were found. This analysis, combined with STEPL results, indicates that sediment loading is most likely coming from urban watershed sources such as stormwater runoff from impervious areas. Figure 55

provides a breakdown of the percent of annual runoff attributed to the various urban land uses. Transportation, or roads, contribute the highest level of runoff on an average annual basis. Pollutant loading from STEPL by model catchment are provided in Figure 56 through Figure 58 and the percent of developed land cover per model catchment is provided in Figure 59.

Figure 55. Percent total runoff from STEPL by urban land uses in the East Branch DuPage River subwatershed.

The East Branch DuPage River includes one fecal coliform impaired segment. There are no identified impairments upstream and therefore this implementation plan assumes that sources of fecal coliform are found in the direct drainage area of the impaired segment. Wastewater and stormwater runoff are the most likely source of fecal coliform to this impaired segment, although potential cross connections between sanitary sewers and storm sewers could also be present.

Figure 56. Annual phosphorus loading from STEPL in the East Branch DuPage River subwatershed.

Figure 57. Annual sediment loading from STEPL in the East Branch DuPage River subwatershed.

Figure 58. Annual BOD loading from STEPL in the East Branch DuPage River subwatershed.

Figure 59. Developed land cover in the East Branch DuPage River subwatershed (NLCD 2011).

West Branch DuPage River Subwatershed

Similar to the East Branch DuPage River, urban land uses contribute the majority of watershed pollutant loads in the West Branch DuPage River subwatershed. Cropland and other undeveloped land uses contribute between two and 18% of the total pollutant load. The streambank erosion analysis found no major areas of erosion within the watershed, therefore the majority of sediment loading is most likely coming from urban watershed sources such as stormwater runoff from impervious areas. A breakdown of urban runoff sources in the watershed is provided in Figure 60. Transportation, or roads, contribute the highest level of runoff on an average annual basis. Pollutant loading from STEPL by model catchment are provided in Figure 61 through Figure 63, and the percent of developed land cover per model catchment is provided in Figure 64.

Figure 60. Total runoff from STEPL by urban land use in the West Branch DuPage River watershed.

The West Branch DuPage River is impaired for fecal coliform along five segments starting in the headwaters. Stormwater and wastewater are the primary sources of fecal coliform in this subwatershed. Two fecal coliformimpaired reaches do not have any wastewater (GBK-14 and GBKA). These two reaches demonstrate the potential for stormwater only to cause impairments, although there is the possibility of cross connections between sanitary sewers and storm sewers. The same two headwater reaches are also impaired for low dissolved oxygen. Low dissolved oxygen conditions are primarily due to habitat/channel geometry and sediment oxygen demand (SOD). SOD is in part a result of organic matter decomposing within the stream channel. Reduction in watershed loading of phosphorus, sediment, and BOD will work towards reductions in SOD over time. In the case of GBK-14, additional evaluation of conditions contributing to low dissolved oxygen is needed. Specifically, sampling along the length of the segment is needed as well as monitoring of the outflow from the large retention pond in the upper reaches.

Figure 63. Annual BOD loading from STEPL in the West Branch DuPage River subwatershed.

Lower DuPage River Subwatershed

The Lower DuPage River subwatershed is influenced by contributions from the East Branch and West Branch of the DuPage River. Two segments along the Lower DuPage River are impaired for fecal coliform and either low dissolved oxygen or chloride. There are no fecal coliform impairments identified for the reaches that are directly upstream of the Lower DuPage River. In addition, there is no identified chloride impairment immediately upstream. Therefore, this implementation plan assumes that sources of pollutants affecting these impairments are located in the direct drainage areas to the impaired segments. Stormwater, wastewater, and agricultural runoff are the primary sources of fecal coliform and chloride in the subwatershed.

The low dissolved oxygen impairment (GB-16) is the result of point source discharges, SOD, and upstream contributions. In addition, loads from the East Branch and West Branch are influencing the headwater of GB-16 with high phosphorus concentrations and lower dissolved oxygen. The cause of low dissolved oxygen conditions within the watershed is not yet clearly understood. It is likely a combination of stormwater, wastewater, SOD, and in-channel habitat. Permitted facilities in the watershed are being required to reduce point source nutrient loading as part of a basin-wide permit; they are also funding several habitat improvement projects. Loading of biochemical oxygen demand (BOD) and potential reductions is provided in this implementation plan to help inform implementation activities.

Annual loads by source category are summarized in Figure 65, Figure 66, and Figure 67 for total phosphorus and total BOD (pounds per year) and sediment (tons per year), respectively. While urban sources of pollutants are dominant in the East and West Branch DuPage River subwatersheds, cropland contributes much more of the total phosphorus and BOD loading, and is the dominant source of sediment in the Lower DuPage River subwatershed. The streambank erosion analysis found no major areas of erosion within the watershed. This, combined with STEPL results indicate that sediment loading is most likely coming from cropland areas in the Lower DuPage River watershed. A further break down of runoff being generated in urban areas is provided in Figure 68. Urban runoff in the Lower DuPage River subwatershed is predominantly from transportation, or roads. Pollutant loading from STEPL by model catchment are provided in Figure 69, through Figure 71, and the percent of developed land cover per model catchment is provided in Figure 72.

Salt Creek Subwatershed

A separate planning study is being completed by CMAP for the Salt Creek watershed. Please see <u>http://www.cmap.illinois.gov/programs/lta/lower-salt-creek</u> for more information.

8.3 Critical Areas

Successful implementation begins with identifying and focusing resources in critical areas. Critical areas are the focus of outcome-based plans because they represent those areas where project funding will provide the greatest environmental benefit. In this case, critical areas are those areas where there is a high risk for delivery of pollutant loads. The critical area analysis recognizes that achieving water quality improvements requires a mix of practices across multiple landscapes.

Critical areas for implementation of nutrient and sediment reductions were determined on a model catchment scale; each of the catchments within a subwatershed (East Branch, West Branch, Lower) were rank ordered from high to low based on phosphorus, BOD, and sediment yields (see Appendix I). Salt Creek critical areas are being identified in a separate planning study by CMAP. A score was assigned to each catchment based on the rank order for each pollutant. Each pollutant score was totaled for a final critical area score in each catchment (Figure 73 through Figure 75). High scores represent high pollutant loadings per acre of watershed and are therefore considered primary critical areas for implementation. Critical areas present opportunities to develop smaller-scale implementation plans that can include field-based observations and landowner involvement. These smaller-scale implementation plans will help to refine implementation activities and focus resources.

Critical areas for chloride reductions are not specifically identified in the GB-11 catchment. Since application of road salt and de-icing chemicals is the primary contributor of chloride loading (CDM 2007), all impervious areas that are treated with de-icing chemicals are considered critical source areas for chloride reduction and management in the GB-11 catchment.

Critical areas that address sources of fecal coliform require additional monitoring to define. Sources of fecal coliform are widespread and often intermittent. Some sources pose a greater risk to human health than others. Understanding the different source contributions and their potential risk to human health is important to overall TMDL implementation and prioritizing implementation activities that address the recreational use impairments due to fecal coliform. Monitoring that will help define critical areas include synoptic sampling, sanitary surveys, and microbial source tracking, described below.

Synoptic Sampling

Sampling for fecal coliform along the length of the impaired segment as well as upstream can be used to identify fecal coliform hotspots in the contributing drainage area. Synoptic sampling is recommended along each reach under different flow conditions. Results of this sampling will guide the geographic area where sanitary surveys should be completed.

Sanitary Survey

A sanitary survey is often used to identify fecal coliform sources in a watershed. For the purpose of fecal coliform source identification, sanitary surveys consist of observational data collection of potential sources of fecal coliform in a watershed. Data collected may include: number of pets and wildlife; distance and condition of public restrooms from impaired waters; location, number and condition of waste collection facilities (e.g., trash cans, pet waste stations, dumpsters); identification of improperly placed or failing infrastructure; septic system evaluation in unsewered communities; quantity of pet and wildlife excrement in open areas; and other potential sources and/or conveyance systems. Surveys should be conducted on a regular frequency under varying weather conditions.

Microbial Source Tracking

Microbial source tracking (MST) is a useful tool to help differentiate sources of fecal contamination. Fecal bacteroidetes, or fecal indicator bacteria, are used in MST. The use of fecal indicator bacteria is advantageous

as they are abundant in the intestinal tract of warm blooded animals and various strains are known to be associated with specific hosts (human, bird, dog, deer, etc.), allowing test results to determine the likely source of contamination. While human sources of fecal pollution are critical to eliminate, it is also important to minimize other sources that can cause illness in humans, although the actual risk associated with these other sources may fall within "acceptable" levels. MST is not able to determine exact source location. Best professional judgement from sanitary surveys and local knowledge can provide an initial assessment of source and location.

Figure 73. Critical areas for implementation in the East Branch DuPage River subwatershed.

Figure 74. Critical areas for implementation in the West Branch DuPage River subwatershed.

Figure 75. Critical areas for implementation in the Lower DuPage River subwatershed.

8.4 Best Management Practices

Both point and nonpoint sources of pollution will need to be addressed in order to achieve long-term, successful improvements to water quality, however only nonpoint source controls and BMPs are eligible for Section 319 funding. A suite of both structural and nonstructural BMPs will be needed to address sources contributing to impairments in the watershed. BMPs are included to address TMDL pollutants (i.e., fecal coliform, chloride, and low dissolved oxygen conditions) as well as other sources of pollutants contributing to nutrient and sediment loading in the watershed.

8.4.1 Nonstructural Management Opportunities

Nonstructural management opportunities are often classified as pollution prevention or source control BMPs since they aim to prevent runoff from a site. Source control BMPs reduce the exposure of materials to runoff, and thereby reduce the amount of pollutants picked up by runoff. It is typically more cost-effective to prevent pollution from entering runoff rather than treat either the collected runoff flow or waterbodies affected by stormwater discharges (UDFCD 2010). Traditional source control methods include land use or site planning practices, as well as ordinances that aim to prevent runoff. During the early stages of implementation, efforts should first focus on the refinement of existing programs to verify that the existing programs target sources effectively. Nonstructural management opportunities include:

- Ordinance development
- Street and parking lot sweeping
- Pet waste education and outreach
- Wildlife implementation practices
- Chloride reduction management planning and education
- Septic system maintenance and inspection

Ordinance Development

Many communities are undertaking efforts to improve current development ordinances, stormwater regulations, and environmental protection ordinances. Most developed areas within the DuPage River watershed already have ordinances in place to protect water quality. For example, the Will County watershed management ordinance (WMO) states:

"developers must provide the District with the boundaries, extent, function, value, and quality of all wetlands on site. Development that impacts wetlands is discouraged by the WMO, but mitigation is allowed in some cases. The District's preferred method for wetland mitigation, as written in the WMO, is payment to a wetland mitigation bank. The WMO encourages existing riparian functions to be protected. Mitigation practices such as streambank stabilization and native vegetation planting are required."

Local land use planning requirements and stormwater regulations could be strengthened to more fully address the activities that are causing impairments. Many of the components of the DuPage County countywide stormwater and flood plain ordinance (2012) could be incorporated to strengthen existing requirements and regulations including:

- Buffer requirements
- Stormwater quality treatment requirements
- Stormwater volume control
- Stronger new development ordinances

Additional components may include provisions that encourage green infrastructure as a method of meeting runoff, volume control and stormwater detention requirements, ordinances on private salt piles, and the formation of a formal pet waste program. Areas of existing agricultural use are likely to become developed during implementation of this plan, and therefore ordinances that address new imperviousness and retrofitting existing untreated sites are important.

Street and Parking Lot Sweeping

Streets and parking lots accumulate significant amounts of pollutants, including sediment, road salt, trash, organic material, and debris. Street sweeping can decrease the accumulation of pollutants in catch basins while improving curb appeal and controlling dust. Municipal street sweeping programs can target regulatory requirements and minimize pollutants from roadways, a primary source of sediment and organic material in the watershed.

An effective street sweeping program can remove several tons of debris per year while minimizing pollutants in stormwater runoff. Studies have shown that street sweeping programs can reduce sediment and nutrients, depending on the frequency and timing of sweeping and the sweeping technology used. Sweeper type and frequency will dictate the expected removal efficiency depending on the timing, frequency, and the sweeping technology used. There are three types of sweepers: the mechanical broom, regenerative-air, and vacuum-assist. The frequency of sweeping affects the pollutant removal efficiency. Weekly sweeping can remove up to 31% of solids and 8% total phosphorus (CWP 2008).

Pet Waste Education and Outreach

Pet waste management can reduce nutrient and bacteria loadings in developed areas. Successful pet waste programs are often composed of (1) codified ordinance to penalize illicit deposition of pet feces, (2) public outreach, and (3) pet waste stations in public parks and recreation areas. Some pet waste programs also include municipal pet registries that are typically created for public health concerns. Recommended implementation activities are intended to create a comprehensive, coordinated, and robust pet waste education and outreach program. Priority areas for domestic waste implementation practices are areas with lots of pets and a high degree of impervious cover such as highly developed areas. Recommendations for developing a pet waste program include the following:

• City code that penalizes pet feces deposition in public areas. City code should be developed to prohibit deposition of pet feces in public areas, if not already in place. Code should target public areas (e.g., municipal parks) and areas served by storm sewers. In the counties, which are rural, ordinance should focus on public recreation areas, especially those adjacent to waterways. City code or county ordinance, along with civil and monetary penalties, should be cited on signage at public recreation areas and at pet waste stations. Monetary penalties may serve as a disincentive from pet waste mismanagement. For example, the City of Geneva's local ordinance states:

"It shall be unlawful for an owner to fail to immediately remove excrement deposited by [his/her] pet upon the public ways, or within the public places of the city, or upon the property of any other person without that person's consent. When accompanying an animal off of [his/her] property, the owner or [his/her] agent shall have on [his/her] person a plastic or paper bag or container suitable for the removal of such excrement. Any person violating any provisions of this chapter shall be guilty of a petty offense and may be fined not less than twenty five dollars (\$25.00) nor more than five hundred dollars (\$500.00) for each separate and distinct violation."

The Forest Preserve of DuPage County also regulates pet waste pickup in forest preserves and have enforcement mechanisms that include a fine up to \$120 and court costs for improperly disposing of dog waste. Enforcement is critical to a successful pet waste management program.

- Establish a network of pet waste stations in public recreation areas. Pet waste stations should be established in all parks and other recreation areas. The stations should include signs to identify the stations and how to use the stations; if code or ordinance is enacted to prohibit pet waste mismanagement, the code or ordinance should also be cited on signage.
- Develop an education campaign. A campaign refers to a coordinated, comprehensive outreach effort that integrates a variety of education and outreach techniques. Campaign development starts with a baseline survey to understand existing dog owner behaviors and perceptions, uses survey information to craft effective messages delivered using formats tailored to target audiences, and follows up with a

post-campaign survey to determine effectiveness. This campaign can support any regional or local stormwater management programs.

Because pet waste programs are a popular component of stormwater management programs, there are a great deal of materials available for use. DuPage County Stormwater Management, for example, has developed an educational brochure on proper pet care

(https://www.dupageco.org/EDP/Stormwater Management/Docs/Brochures and Applications/53390/). There are not a lot of data available about the effectiveness of these programs with changing behavior and improving water quality conditions, however. Assumptions related to the amount of dog waste diverted from the stream can be made based on bag usage from pet waste stations. Another evaluation mechanism used by these programs is changes in awareness, although a more aware target audience does not always translate into an audience that exhibits behavior changes.

Wildlife Implementation Practices

Wildlife such as raccoons, deer, and birds are a source of fecal bacteria in urban areas. Priority areas for implementation include high-density wildlife populations near or in riparian areas with unstable banks or poor riparian vegetation and recreational areas where food/dumping might attract wildlife. Recommended implementation activities include outreach and education on impacts of feeding wildlife near riparian areas and riparian buffers to reduce wildlife access.

Chloride Reduction Management Planning and Education

Road salt for snow removal was the primary contributor to chloride water quality standard exceedances in the watershed. Therefore, it is incumbent that those who use road salt use it as efficiently as possible, applying the right amount at the right time as required for any given winter storm (e.g., frost events, snow fall, freezing rain, and sleet) situation. In 2007, DRSCW completed the *Chloride Usage Education and Reduction Program Study*. The study compiled information on chloride usage within the watershed to calculate an estimated annual chloride load. The following activities were recommended for chloride reduction in the watershed:

- Public education, staff training, and improved salt storage and handling practices
- Watershed-wide implementation of pre-wetting and anti-icing programs
- Consideration of alternative non-chloride products such as acetate deicers and beet and corn derivatives
- Chloride monitoring in streams to demonstrate program effectiveness

The DRSCW also provides the following guidance for both salt storage, to minimize any loss of road salt, and in application, to apply the correct amount of salt and to ensure that the salt stays on the pavement surface until it has served its purpose. In addition, the DRSCW has model ordinance language for private section salt storage.

- Salt storage best management practices minimize the loss of road salt due to precipitation onto stockpiles, or water running into the storage area and to protect the ground upon which the salt is stored. The following best practices will be required for all class four, five and six dischargers in the watershed but are recommended for all facilities that store road salt:
 - 1. Road salt must be stored on an impermeable pad at all times. Temporary storage on permeable surfaces is not acceptable. All pads must be under cover to eliminate exposure to precipitation.
 - 2. Pads must be constructed so that rain water or other precipitation does not drain onto the pad. Any rain that drains onto the pad must be drained to a collection point, preferably a specially designed sump area.
 - 3. Salt that is temporally not stored under a permanent structure must be covered by tarping, for example, except when the stockpile is in active use.
 - 4. If the agency regularly stores smaller salt piles (5,000 tons or less) outside of a permanent structure the agency with such stockpiles should develop a plan to construct covered storage capable of containing an average year's use of salt.
 - 5. All salt storage facilities must have policies in place for "good housekeeping" when salt is being placed into storage, and moved from storage into trucks (either for winter maintenance

purposes or for movement to other storage facilities). These policies must reflect the particular conditions on site, but should be aimed at ensuring that as little salt as possible is spilled during these trans-shipment processes, and that any salt which is spilled should be swept up and returned to storage in a timely manner to minimize any loss of salt.

- 6. All employees involved in salt storage must undergo training annually on best practices for road salt storage.
- Additional information on salt storage is available in the Salt Institute "Safe and Sustainable Salt Storage Handbook" which may be accessed at: <u>http://www.saltinstitute.org/wp-</u> <u>content/uploads/2013/09/Salt-Storage-Handbook-2015.pdf</u> (accessed on 5/10/17).
- Local units of government are recommended to adopt a storage ordinance covering private salt piles. Examples of such ordinances can be found at <u>http://drscw.org/wp/model-</u> ordinances/.
- Salt application best management practices help to ensure that only as much salt as needed is placed upon the road during winter maintenance operations. The purpose of road salt in such operations is not to melt snow or ice, but rather to prevent the bond of snow or ice to the pavement. If snow or ice has already bonded to the pavement the purpose of the salt is to break the bond.

The best practice for efficient salt application during winter maintenance is to anti-ice, or to place road salt (in either liquid or solid form, but more often as a liquid brine) on the road surface prior to the start of a winter event, thus providing a protective layer that prevents snow and ice from bonding to the road surface. However, experience has shown that it takes several years for an agency to transition from more traditional winter maintenance operational strategies to anti-icing, so a series of actions leading toward anti-icing could be implemented. The following best practices will be required or recommended for dischargers who run snow fighting operations – these best practices are not pertinent to those dischargers that are simply and solely salt storage facilities. They are, however, somewhat applicable to all classes of dischargers, to the extent that all of these classes clear snow and ice from their own facilities.

- All salt spreading equipment, whether designed to spread dry road salt, pre-wet road salt or salt brine, must be calibrated at least annually. Whenever the hydraulics on a truck are adjusted or repaired, the spreader equipment will need recalibration. Records of the calibration results must be maintained for each piece of spreading equipment. Proper calibration of equipment can reduce salt application by 50% or more, depending upon how far out of calibration the equipment was originally.
- 2. Using pre-wet road salt allows an agency to reduce salt application rates by 30%. Pre-wetting can be accomplished in two ways by applying liquids to the salt stockpile, or by applying liquids by way of the spreading equipment as the salt is deposited on the road. It is generally accepted that the second method is more efficient, but requires modification to spreading equipment, and that an agency have storage capacity for liquid chemicals (most typically salt brine, but other chemicals can also be used). Agencies must make use of pre-wetting, either using treated salt in the stockpile, or preferably by use of liquids applied on the truck during the spreading process.
- 3. The quantity of salt applied to the road should vary according to the pavement temperature. Accordingly, agencies must have equipment that allows them to measure the pavement temperature. While it may take some time to equip the complete winter maintenance fleet with temperature measuring devices, agencies must, at the start of the variance period, have pavement temperature sensors on enough vehicles to provide operational information during storms that allow salt application rates to be adjusted to the most efficient levels. In addition, agencies must have a plan developed at the start of the variance period to equip the whole winter maintenance fleet with such sensors, and this plan must be completed by the end of the variance period. This requirement is a pre-requisite for the requirement detailed in item 4 below.
- 4. Agencies should adopt or develop a chart with suggested application rates that are a function of storm type and pavement temperature. An example of such a chart is available in the *"Manual of Best Management Practices for Road Salt in Winter Maintenance"* referenced above. Additionally, agencies should develop a methodology whereby they can determine

whether each truck in their fleet applied salt at the recommended rate, and if not, why the variation from the recommended rate occurred and what needs to be changed in their procedures to be sure that the variation only occurs when strictly necessary. Varying application rates according to pavement temperature allows for reductions in total applications of as much as 50% or more.

- 5. As pavement temperatures decline, salt takes longer to go into solution and thus to become effective. Practice has shown that once pavement temperatures drop below 15° F the time for salt to go into solution is such that it is often plowed off the road by subsequent operations before it can be effective. Clearly, this is not an optimal use of road salt. Agencies must develop procedures for those rare situations when pavement temperatures drop below 15° F, including methods to track when these situations occur and what actions were taken under these extreme conditions. Avoiding application of salt in conditions where pavement temperatures are too low obviously results in a 100% reduction in salt usage for those conditions.
- 6. Agencies must have in place a methodology to track how much road salt was applied during each storm, together with some measure of how operationally severe the storm was. While this methodology does not result in a reduced application rate *per se*, it does address the issue that "if you do not measure it you cannot manage it."
- 7. Anti-icing has been shown to allow agencies to achieve their desired levels of service using about a quarter of the salt that a more traditional de-icing operational strategy requires to achieve the same levels of service (i.e., as much as a 75% reduction in salt application totals). Accordingly, agencies must develop a plan with clearly delineated milestones for the implementation of anti-icing in their agency.
- 8. All employees involved in winter maintenance operations must undergo annual training in best practices in the use of road salt in such operations.

DuPage County has a website designated to <u>winter snow and ice removal</u> that includes additional information on municipal BMPs. DRSCW has also led <u>chloride reduction</u> workshops for many years in the watershed and provides technical resources and educational materials. Workshops on chloride management are also held in Will County.

Septic System Maintenance and Inspection

Septic systems that are properly designed and maintained should not serve as a source of contamination to surface waters. However, septic systems do fail for a variety of reasons. Common soil-type limitations which contribute to failure include seasonally high water tables, compact glacial till, bedrock, and fragipan. When these septic systems fail hydraulically (surface breakouts) or hydrogeologically (inadequate soil filtration) there can be adverse effects to surface waters (Horsely and Witten 1996). Septic systems contain all the water discharged from homes and business and can be significant sources of pollutants.

BMPs to reduce fecal coliform loads from septic systems include system upgrades/replacement, maintenance, inspection programs, and public education. The most cost-effective BMP for managing pollutant loading from septic systems is regular maintenance. U.S. EPA recommends that septic tanks be pumped every 3 to 5 years depending on the tank size and number of residents in the household (U.S. EPA 2002). When not maintained properly, septic systems can cause the release of pathogens, as well as excess nutrients, into surface water. Annual inspections, in addition to regular maintenance, ensure that systems are functioning properly. An inspection program would help identify those systems that are currently connected to tile drain systems or storm sewers and those that may be failing. Inspections would also help determine if systems discharge directly to a waterbody ("straight pipe"). Additional point of sale inspections, or inspections when a property is sold and purchased, can improve the baseline understanding of septic conditions and decrease occurrences of leaks potentially contributing to fecal loading in the watershed. These may include a soil boring to determine if the soil has adequate separation, and an examination of the inside of the tank after it has been pumped.

Education is a crucial component of reducing pollution from septic systems. Education can occur through public meetings, mass mailings, and radio and television advertisements. An inspection program can also help with

public education because inspectors can educate owners about proper operation and maintenance during inspections.

8.4.2 Structural Management Opportunities

Structural BMPs can be incorporated in urban landscapes to capture, infiltrate, filter, and treat stormwater runoff. These BMPs can be integrated into redevelopment projects, implemented as part of a stormwater retrofit strategy, or required for new developments. In addition, significant areas in agricultural production are present and contributing to sediment and nutrient loading in the Lower DuPage River watershed. Agricultural BMPs are included for these land uses.

Green Infrastructure Retrofitting

The use of green infrastructure, especially those practices that reduce the volume of runoff from urban areas, can address pollutant loads from existing developed areas and prevent or mitigate stormwater runoff volume. A number of green infrastructure practices may be appropriate, considering land use constraints, and are likely to be effective for reducing watershed loadings of bacteria, nutrients, sediment, and organic matter.

Offering considerable versatility with design and implementation, green infrastructure concepts can be incorporated into new and existing developments and can be less cost intensive than traditional, structural stormwater management systems (U.S. EPA 2007b). Furthermore, green infrastructure practices offer an innovative way to integrate stormwater management into natural landscapes, minimizing alterations to the natural hydrologic regime and reducing site runoff. Implementation of green infrastructure practices can also encourage groundwater recharge, and decreases surface erosion and pollutant transport. Additional benefits of green infrastructure include improved greenways and enrichment of natural environmental aesthetics within the urban setting.

When selecting the most appropriate BMPs for a specific site or drainage area, site-specific conditions (e.g., land availability, slope, soil characteristics, climate condition, utilities, and characterization of contributing drainage including imperviousness) must be taken into consideration. Care must also be given to ensure the proper treatment identifies any site concerns or hazards. For example, infiltration should not be encouraged in areas surrounding stormwater hot spots, such as automotive repair shops, gasoline stations, or industrial areas where groundwater contamination or pollutant transfer is a possibility.

Figure 76. Green infrastructure examples: top - residential rain garden; bottom - permeable pavement.

The use of green infrastructure is quickly advancing and new

research is supporting the use of varying BMPs for pollutant removal, provided the systems are constructed and maintained. Examples of green infrastructure BMPs include rain gardens, bioretention/biofiltration, permeable pavement, and green roofs.

The <u>Illinois Urban Manual</u> includes design information and practice standards for use throughout the state for these and other stormwater management practices. The most recent summary of BMP removal efficiencies provided by the International Stormwater BMP Database (Clary et al. 2017) shows on average that many BMPs are able to remove fecal bacteria from stormwater to some degree (Figure 77). Those practices that include infiltration or filtration such as biofiltration, and traditional practices such as sand filters, have the best opportunity

to reduce fecal coliform loads. Practices such as wetlands and ponds can also remove fecal coliform, however practices must be designed and maintained to deter wildlife.

Figure 77. Fecal coliform concentrations in influent and effluent for various BMPs. Figure from Clary et al. 2017.

Stormwater Ponds and Detention Basins

Stormwater ponds have traditionally been constructed to provide rate control and flood protection. Depending on the pond design, additional water quality benefits can also be realized. Ponds rely on physical, biological, and chemical processes to remove pollutants from incoming stormwater runoff, in particular nutrients and sediment. Ponds designed to hold back water for longer periods of time will reduce pollutants to higher levels. Different types of ponds exist including dry and wet ponds; these ponds can include pretreatment cells where sediment is allowed to settle out. Fecal coliform removal has been documented (see Figure 77), however ponds have also been shown to be sources of fecal bacteria. Design, maintenance, and monitoring is needed to determine a pond's ability to reduce fecal coliform loading.

A naturalized detention basin is similar to a conventional pond but is enhanced with relatively flat side slopes and diverse plant communities along aquatic benches and within buffers. These basins are intended to provide multiple benefits including pollutant removal, flood prevention, hydrologic stability, and creation of habitat. In addition, naturalized detention basins can prevent shoreline erosion, increase water clarity, reduce water temperatures, and discourage congregation of geese. They are also generally thought to be safer than conventional wet ponds without benches and require less long-term maintenance.

Wetland Creation and Restoration

Wetland are a natural storage feature that slows and filters water, increasing flood resiliency. They have the ability to reduce fecal bacteria, nutrient and sediment loading to nearby waterways, moderate water temperature, and provide habitat for plants and wildlife. Wetland soils and plants provide carbon storage, helping to moderate levels of carbon dioxide in the atmosphere. Wetland restoration is the renewal of natural and historical wetlands that have been lost or degraded. When selecting wetland restoration projects and locations, diversity of wetland and long term maintenance should be considered. Special consideration should

be given to increasing the diversity of wetlands and their functions as relate to water quality. Wetlands restoration projects can also be combined with regional greenways and trail networks to increase public access and education potential. Long term maintenance cost for wetlands may include invasive species control, burning, herbicide application, and mowing (The Conservation Foundation 2011).

Riparian Area Management

Preserving the natural vegetation along a stream corridor can mitigate pollutant loading associated with human disturbances. The root structure of the vegetation in a buffer enhances infiltration and subsequent trapping of pollutants. However, the buffers are only effective in this manner when the runoff enters the buffer as a slow moving, shallow sheet. Concentrated flow in a ditch or gully will quickly pass through the buffer offering minimal opportunity for retention and uptake of pollutants.

Even more important than the filtering capacity of the buffers is the protection they provide to streambanks and steep slopes. The rooting systems of the vegetation serve as reinforcements in soils, which help to hold material in place and minimize erosion. Due to the increase in stormwater runoff volume and peak rates of runoff associated with development, stream channels are subject to greater erosional forces during stormflow events. Thus, preserving natural vegetation along stream channels minimizes the potential for water quality and habitat degradation due to streambank erosion and enhances the pollutant removal of sheet flow runoff from developed areas that pass through the buffer.

Riparian buffers/filter strips should consist of native species and may include grasses, forbs, shrubs, and trees. Higher removal rates are provided with greater buffer widths. Maintenance of a riparian buffer should be minimal, but may include items inspection, minor grading to prevent short circuiting, and replanting/reseeding dead vegetation following premature death or heavy storms. The following activities could take place as part of a riparian area management program:

- Adopt and/or implement buffer ordinances for new development or redevelopment
- Document the presence of gullies or invasive species that could contribute to water quality concerns

Stream Restoration

Restoration of channelized streams and rivers and daylighting streams that have been buried in storm sewers or tunnels can greatly enhance the stream function, habitat, and water quality. A natural channel design is typically meandering with connection to a floodplain. In urban areas, this type of channel is challenging due to space constraints and the need to protect private property and infrastructure. In these cases, identifying opportunities to daylight a portion of the streamflow and creating habitat can be successful strategies.

One key method to restoring a stream is dam removal. Dams can contribute to stagnant pools where dissolved oxygen is low. Additionally, many of the impoundments caused by dams in the DuPage River watershed resulted in large amounts of sediment to settle out of the water column and cover natural habitat (Hammer et al. 2003). For example, the Churchill Woods dam was lowered in 2011 to improve dissolved oxygen and water quality conditions in the East Branch DuPage River as well as provide for fish passage.

Streambank erosion from unstable or channelized streambanks can also be addressed by many different BMPs including:

- Engineering controls such as armoring with materials that straighten the banks and deflection of the water course with rock or log structures.
- Vegetative stabilization and restoration of riparian areas can reduce peak flows from runoff areas and channel velocities directing runoff. Using vegetative controls also enhance infiltration, which reduces high flows that cause erosion.
- **Natural channel restoration** that establishes meanders and natural flow complexity and connects the stream channel with the floodplain.

Agricultural BMPs

Agricultural runoff is an important source of sediment and nutrients loading in portions of the watershed. Various agricultural practices can be used to reduce pollutant loading associated with crop production including:

- **Conservation tillage** is identified as a primary BMP for nutrient reduction in the Illinois Nutrient Loss Reduction Strategy (NLRS). Conservation tillage is any tillage practice that results in at least 30% coverage of the soil surface by crop residuals after planting.
- Fertilizer and nutrient management addressed application rates, methods, and timing as described in the NRLS and according to the 4Rs Right Source, Right Rate, at the Right Time, and in the Right Place nutrient stewardship program. Additional information on the 4Rs can be found at http://www.nutrientstewardship.com/4rs/.
- **Cover crops** (winter) are identified in the NRLS as an important management practice to reduce erosion and phosphorus loading. Grasses and legumes may be used as winter cover crops to reduce soil erosion and improve soil quality.
- **Filter strips** include perennial vegetation and trees that can filter runoff from adjacent cropland, provide shade and habitat for wildlife, and reinforce streambanks to minimize erosion.

8.4.3 BMP Removal Efficiencies and Costs

Table 65 summarizes the removal efficiency and costs of various BMPs that could be used to achieve necessary load reductions in the watershed.

Table	65.	BMP	removal	efficiencies
1 4010			101110101	011101010100

	Re	emoval E	fficiency (%)	a			
BMP	Phosphorus	BOD	Sediment	Fecal Coliform	Cost ^b

8.5 BMP Implementation

As summarized in Section 8.2, stormwater sources contribute the vast majority of pollutant loading to the East and West Branch DuPage River subwatersheds. Much of the pollutant loading to the Lower DuPage River is from urban sources with the exception of sediment, which is mostly coming from cropland (Figure 66). The potential impacts of several BMPs were evaluated across a range of implementation levels.

Reductions in TP, sediment, and BOD associated with treatment of runoff from various land uses were quantified using STEPL. No specific load reductions targets are available for these pollutants, therefore multiple implementation scenarios to treat runoff were simulated to present a range of possible reductions in each subwatershed. There are many different BMP scenarios that could be used to achieve pollutant load reductions, this plan provides a framework and example scenarios.

The extent of BMP implementation to meet load reductions needed for fecal coliform and chloride are not quantified. BMP removal efficiencies for fecal coliform is extremely variable, with filtration practices being the most promising. Point source reductions from WWTPs and programmatic activities will also be needed to meet fecal coliform load reductions. Chloride reductions will be the result of source control; there are no practical BMPs that can remove chloride once it is dissolved into water. Addressing the conditions that are contributing to low dissolved oxygen will be a combination of programmatic activities, point source reductions, in-stream restoration, and reductions in phosphorus and loading of organic material that are contributing to sediment oxygen demand. Lastly, DRSCW members provided planned site-specific projects that will help to reduce and assimilate pollutant loads in the East and West Branch DuPage River subwatersheds addressed in this TMDL.

8.5.1 East Branch DuPage River Subwatershed

BMPs are needed in the East Branch DuPage River to address fecal coliform, sediment, and nutrient impairments. In addition, as the East Branch DuPage River discharges into the Lower DuPage River, phosphorus reductions and compliance with dissolved oxygen standards are needed to comply with the GB-16 low dissolved oxygen TMDL.

Fecal Coliform Load Reductions

There is one fecal coliform-impaired segment in the East Branch DuPage River, GBL-10. There are several point sources that discharge to this segment including one CSO. Permit compliance and elimination of the CSO is needed to meet required load reductions. In addition, a sanitary survey (described in Section 8.3) is needed to identify potential sources of fecal coliform in the direct drainage area. This survey, along with additional monitoring, can be used to identify hotspots and focus implementation activities. Disconnecting impervious areas using green infrastructure and other stormwater management practices that utilize filtration can be used to reduce stormwater runoff and associated fecal coliform loading. Programmatic activities described in Section 8.4.1 are also needed.

Nutrient and Sediment Load Reduction Scenarios

In the East Branch, urban sources contribute the vast majority of pollutant loading to the subwatershed (between 97 and 100%). Of these sources, commercial, single family residential, open space, and transportation land use categories contribute the greatest amount. Therefore, for each of these land uses, BMPs were assigned to treat 20, 40, and 60% of the urban runoff being generated (Figure 78). BMPs were selected from STEPL that best aligned with the planned and implemented BMPs in the watershed gathered through a review of existing and current planning efforts and include:

- Permeable pavement applied to commercial land uses
- Bioretention applied to single family residential land uses
- Wetland detention applied to open space land uses
- Extended wet detention ponds applied to transportation land uses

Figure 78. Implementation curves, East Branch DuPage River subwatershed.

Site-Specific Projects from Local Partners

Several site-specific BMPs, costs and timeframes were provided by DRSCW members within the East Branch DuPage River subwatershed (Table 66 and Figure 79). These projects will help reduce and assimilate nonpoint source pollutant loads identified in this TMDL. Specifically, in-river improvements that include building pool riffle sequences will result in increased aeration of the water column, contributing to increasing dissolved oxygen levels in the East Branch DuPage River and meeting the previously approved dissolved oxygen TMDL. In addition, stormwater management activities such as permeable pavement installation and reducing sediment loading from stream banks will reduce the phosphorus and other pollutants to the River that are contributing the sediment oxygen demand, resulting in increased dissolved oxygen. All of these activities will contribute to meeting the headwater conditions of GB-16 in the Lower DuPage for compliance with the GB-16 dissolved oxygen TMDL.

8.5.2 West Branch DuPage River Subwatershed

BMPs are needed in the West Branch DuPage River to address fecal coliform, sediment, nutrient, and dissolved oxygen impairments. In addition, as the West Branch DuPage River discharges into the Lower DuPage River, additional phosphorus reductions and increases in dissolved oxygen conditions are needed to comply with the GB-16 low dissolved oxygen TMDL.

Fecal Coliform Load Reductions

There are three fecal coliform-impaired segments in the West Branch DuPage River: GBK-05, GBK-09, and GBK-14. There are several point sources that discharge directly to these segments. Permit compliance is needed to meet required load reductions. In addition, a sanitary survey (described in Section 8.3) is needed to identify potential sources of fecal coliform in the direct drainage area. This survey, along with additional monitoring, can be used to identify hotspots and focus implementation activities. Disconnecting impervious areas using green infrastructure and other stormwater management practices that utilize filtration can be used to reduce stormwater runoff and associated fecal coliform loading. Programmatic activities described in Section 8.4.1 are also needed.

Nutrient and Sediment Load Reduction Scenarios

In the West Branch, urban sources contribute the majority of pollutant loading to the subwatershed (between 82 to 98%). Of those source, institutional, single family residential, open space, and transportation land use categories contribute the greatest amount. Therefore, for each of these land uses, BMPs were assigned to treat 20, 40, and 60% of the runoff they generate. BMPs were selected from STEPL that best aligned with the planned and implemented BMPs in the watershed gathered through a review of existing and current planning efforts and include:

- Permeable pavement applied to institutional land uses
- Bioretention applied to single family residential land uses
- Wetland detention applied to open space land uses
- Extended wet detention ponds applied to transportation land uses

Results of the three implementation scenarios (20, 40, and 60% implementation) are provided in Figure 80.

Dissolved Oxygen Improvements

Improvements along GBK-14 and GBKA are needed to address dissolved oxygen impairments. There are several options that can be undertaken to achieve the water quality standards addressing either or both reaeration and SOD. SOD reductions can be accomplished through implementation of structural and nonstructural practices in the watershed that will limit organic matter in the stream. Specifically, stormwater management can be used to reduce sediment and nutrient loading and street/parking lot sweeping can be used to reduce leaf litter and grass clippings. In-stream improvements are also likely needed to establish reaeration opportunities. Specifically, the inclusion of riffles and removal of stagnant water sources along these reaches can be used to provide reaeration. One project has been identified along GBK-14 by the DRSCW that will address this need. A similar project is needed for Spring Brook.

Figure 80. Implementation curves, West Branch DuPage River subwatershed.

Site-Specific Projects from Local Partners

Several site-specific BMPs, costs and timeframes were provided by DRSCW members within the West Branch DuPage River subwatershed (Table 67 and Figure 81). These projects will help reduce help to reduce and assimilate nonpoint source pollution loads identified in this TMDL. Similar to the East Branch DuPage River, these activities will contribute to meeting the headwater conditions of GB-16 in the Lower DuPage for compliance with the GB-16 dissolved oxygen TMDL.

8.5.3 Lower DuPage River Subwatershed

BMPs are needed in the Lower DuPage River to address fecal coliform, chloride, sediment, nutrient, and dissolved oxygen impairments. Impacts from upstream improvements to the East and West Branch DuPage rivers will improve phosphorus and dissolved oxygen conditions on GB-16 and potentially chloride conditions on GB-11.

Fecal Coliform Load Reductions

There are two fecal coliform-impaired segments in the Lower DuPage River: GB-11 and GB-16. There are several point sources that discharge to these segments. Permit compliance is needed to meet required load reductions. In addition, a sanitary survey (described in Section 8.3) is needed to identify potential sources of fecal coliform in the direct drainage area. This survey, along with additional monitoring, can be used to identify hotspots and focus implementation activities. Disconnecting impervious areas using green infrastructure and other stormwater management practices that utilize filtration can be used to reduce stormwater runoff and associated fecal coliform loading. Programmatic activities described in Section 8.4.1 are also needed.

Chloride Load Reductions

There is one chloride-impaired segment in the Lower DuPage River: GB-11. There are several point sources that discharge to these segments, and although they do not currently have chloride permit limits, wasteload allocations have been assigned and will be implemented as effluent limits in future permits. Nonpoint source best management practices necessary to reduce chloride loading from impervious areas within the direct drainage area to GB-11 are summarized in Section 8.4.1. While there is no impairment directly upstream of segment GB-11, it is expected that reductions in upstream watersheds will result in reductions in GB-11 due to upstream TMDLs. Reductions required in existing upstream chloride TMDLs are summarized in Table 2 and include a 35% reduction in the West Branch DuPage River and a 33% reduction in the East Branch DuPage River. Because there are limited number of exceedances of the water quality standard in GB-11, the implementation plan relies on expanding the Chloride Reduction Program developed by the DRSCW to the Lower DuPage River watershed, and additional monitoring along with an adaptive management approach. Permit limits for WWTPs in the Lower DuPage River watershed could be considered once non-point source reductions are in place.

Nutrient and Sediment Load Reduction Scenarios

In the Lower DuPage both urban land uses and cropland contribute to nutrient and sediment loading. Therefore, both urban and agricultural BMPs were evaluated in the load reduction scenario. Institutional, single family residential, open space, and transportation land use categories are contributing the largest urban pollutant loadings. Therefore for each of these land uses, BMPs were assigned to treat 20, 40, and 60% of the runoff being generated. BMPs were selected from STEPL that best aligned with the planned and implemented BMPs in the watershed gathered through a review of existing and current planning efforts and include:

- Permeable pavement applied to institutional land uses
- Bioretention applied to single family residential land uses
- Wetland detention applied to open space land uses
- Extended wet detention ponds applied to transportation land uses

Cropland loading was addressed at the same levels of implementation (20, 40, and 60%). An average agricultural BMP removal efficiency of 50% for TSS and TP was applied. No information exists for the removal efficiencies of agricultural BMPs of BOD, therefore these reductions are not quantified. Reductions in BOD, however, are expected. Summary results of the three implementation scenarios (20, 40, and 60% implementation on both urban and cropland) are provided in Figure 82.

Figure 82. Implementation curves, Lower DuPage River subwatershed.

Dissolved Oxygen Improvements

The dissolved oxygen TMDL for GB-16 outlines different options to consider for implementing the TMDL. These options include changes to permit limits for $CBOD_5$ and dissolved oxygen and nonpoint source controls. Reductions in phosphorus (19% based on the difference in the existing condition [1.23 mg/L TP] and the scenario [1 mg/L TP]) are needed as well as increases in dissolved oxygen during critical conditions in the East Branch and West Branch DuPage rivers. Achieving the needed 19% reduction in TP in the East Branch and West Branch will require treatment of between 30 and 40% of the developed lands within those two watersheds. It is expected that reductions in phosphorus, thus reducing organic material, will result in lower SOD rates and coverage over time in the impaired segment. An adaptive management approach is critical in this case to track changes in water quality and adjust implementation activities over time.

8.5.4 Salt Creek Subwatershed

A separate planning study is being completed by CMAP for the Salt Creek watershed. Please see <u>http://www.cmap.illinois.gov/programs/lta/lower-salt-creek</u> for more information.

8.6 **Progress Benchmarks and Implementation Schedule**

Implementation activities will occur in three phases using outcome-based strategic planning and an adaptive management approach. Phase 1 represents the initial 5-year planning window. During this planning timeframe, the focus is on permit compliance, monitoring, identifying specific projects and funding sources, demonstration projects, and building local capacity. Phase 2 (mid-term; 2023-2032) and Phase 3 (long-term; 2033-2040) are designed to build on results from the preceding phase. To guide plan implementation through each phase using adaptive management, water quality benchmarks are identified to track progress towards attaining water quality standards. Progress benchmarks (Table 68) are intended to reflect the time it takes to implement management practices, as well as the time needed for water quality indicators to respond.

Indicator	Target	Segments ^a	Time- frame	Progress Benchmark
	<400 count/100 ml in <10% of	DuPage River (GB-11 and GB- 16)	Phase 1	20% of load reductions
Fecal coliform	samples and <200 count/100ml (30-day	West Branch DuPage River (GBK-05, GBK-09 and GBK-14) Spring Brook (GBKA and	Phase 2	40% of load reductions
	geometric mean of at least 5 samples)	GBKA-01) East Branch DuPage River (GBL-10)	Phase 3	100% of load reductions, full attainment of water quality standards
	For GB-16: March-July > 5.0 min & > 6.25 7-day mean Aug-Feb > 4.0 min, > 4.5 7-day		Phase 1	20% of load reductions
Dissolved oxygen	mean, & > 6.0 30-day mean For GBKA and GBK-14:	Lower DuPage River GB-16) Spring Brook (GBKA) West Branch DuPage River (GBK-14)	Phase 2	40% of load reductions
	March-July > 5.0 min. & > 6.0 7-day mean Aug-Feb > 3.5 min, > 4.0 7-day mean, & > 5.5 30-day mean		Phase 3	100% of load reductions, full attainment of water quality standards
			Phase 1	20% of load reductions
		Lower DuPage River	Phase 2	40% of load reductions
Chloride	<500 mg/L	(GB-11)	Phase 3	100% of load reductions; full attainment of water quality standards.
Nutrients and sediment	Not applicable	Not applicable	Phase 1 Phase 2 Phase 3	Not applicable

Table 68. Progress benchmarks for pollutants of concern

a. Progress benchmarks are not provided for Salt Creek. A separate planning study is being completed by CMAP for the Salt Creek watershed.

A schedule of implementation activities and associated milestones are provided in Table 70. This implementation schedule spans the entire DuPage River watershed, including areas with existing 319 approved watershed plans (Table 64). In areas with such plans, the smaller, HUC12 plans take precedence over this implementation plan. In addition to implementation of these plans, DRSCW, a group of permitted facilities and stakeholders, have agreed to complete a series of water quality and habitat improvement projects. These projects are provided in Table 69 and are part of a series of special conditions included in facility NPDES permits (see Appendix G for the full set of special conditions). This implementation plan assumes the projects will be completed according to their assigned completion dates. More information on DRSCW is provided in Section 8.10.

Project Name	Completion Date	Short Term Objectives	Long Term Objectives
Oak Meadows Golf Course stream restoration	December 31, 2017	Improve aquatic habitat (QHEI), reduce inputs of nutrients and sediment	Raise miBi
Fawell Dam Modification	December 31, 2018	Modify dam to allow fish passage	Raise fiBi upstream of structure
Spring Brook Restoration and dam removal	December 31, 2019	Improve aquatic habitat (QHEI), reduce inputs of nutrients and sediment	Raise miBi and fiBi
Fullersburg Woods dam modification	December 31, 2021	Improve DO, improve aquatic habitat (QHEI)	Raise miBi and fiBi
Fullersburg Woods dam modification area stream restoration	December 31, 2022	Improve aquatic habitat (QHEI), reduce inputs of nutrients and sediment	Raise miBi and fiBi
Southern West Branch Physical Enhancement	December 31, 2022	Improve aquatic habitat (QHEI)	Raise miBi and fiBi
Southern East Branch Stream Enhancement	December 31, 2023	Improve aquatic habitat (QHEI), reduce inputs of nutrients and sediment	Raise miBi and fiBi
QUAL2K East Branch and Salt Creek	December 31, 2023	Collect new baseline data and update model	Quantify improvements in watershed. Identify next round of projects for years beyond 2024.
NPS Phosphorus Feasibility Analysis	December 31, 2021	Assess nonpoint source performance from reductions in leaf litter and street sweeping	Reduce nonpoint source contributions to lowest practical levels

Table 70. Schedule and milestones

Watarbady	Target		Milestones ^a	
Waterbody	Pollutant	2018-2022	2023-2032	2033-2042
All nutrient and sediment impaired waters	Nutrients and Sediment	Identify desired sediment and nutrient load reduction scenario and begin implementation. NPDES permit compliance.	Continue implementation of BMPs needed to meet load reduction scenario chosen in Phase 1. NPDES permit compliance.	NPDES permit compliance. Evaluate implementation effectiveness, adapt if needed. Complete implementation of load reduction scenario.
All fecal coliform impaired waters	Fecal Coliform	Conduct additional monitoring e.g., sanitary surveys to identify sources of fecal coliform. Conduct demonstration stormwater projects. NPDES permit compliance. Create/expand pet waste education and outreach programs.	Evaluate results of NPDES permit compliance. Implement BMPs to best address sources identified in initial sanitary survey (e.g., wildlife management, stormwater management, etc.). Conduct additional monitoring, if needed (e.g., microbial source tracking).	Evaluate effectiveness of BMP implementation in Phase1 and Phase 2. Implement additional BMPs to achieve required load reductions.
GBL-10	Fecal Coliform	Address combined sewer overflows		
GBK-14	Dissolved Oxygen	Conduct additional monitoring to determine the extent of low dissolved oxygen conditions and determine the effect of headwater flow conditions. Identify targeted areas within the stream to increase aeration. Begin implementation of focused education efforts to address loading of organics to the stream from leaf litter, lawn clippings, etc.	Implement project to address low reaeration. Implementation of education and outreach to address loading of organics.	Address remaining reaeration problems. Implementation of education and outreach to address loading of organics.
GBKA	Fecal Coliform	Continue implementation of Spring Brook No.		
	Dissolved Oxygen	Conduct additional monitoring to determine the effect of ponds downstream of Creekside Drive on low dissolved oxygen conditions. Identify targeted areas within the stream to increase aeration. Begin implementation of focused education efforts to address loading of organics to the stream from leaf litter, lawn clippings, etc.	Implement project to increase reaeration in the lower reach. Implementation of education and outreach to address loading of organics.	Implementation of education and outreach to address loading of organics.
		Continue implementation of Spring Brook No.	1 Watershed Plan (see Table 64)	
GBKA-01	Fecal Coliform	Continue implementation of Spring Brook No.		

Waterbody	Target		Milestones ^a	
waterbouy	Pollutant	2018-2022	2023-2032	2033-2042
GB-16	Dissolved Oxygen	Continue to implement dissolved oxygen TMDLs in upstream reaches. Continue to reduce nutrient concentrations in upstream reaches. Further evaluate options for point source pollutant load reductions. Compliance with NPDES permits. Begin implementation of focused education efforts to address loading of organics to the stream from leaf litter, lawn clippings, etc.	Continue to implement dissolved oxygen TMDLs in upstream reaches. Continue to reduce nutrient concentrations in upstream reaches, achieving the target 19% reduction in TP at the headwater of GB-16. Compliance with NPDES permits. Implementation of education and outreach to address loading of organics.	Implementation of education and outreach to address loading of organics.
GB-11	Chloride	Expand chloride reduction efforts by the DRSCW to Lower DuPage River subwatershed, including development of a program targeting private salt application. Continue implementation of existing chloride reduction plan in East and West Branches.	Evaluate implementation of chloride reduction program and adapt as needed.	Evaluate implementation effectiveness of chloride reduction program, adapt as needed. Complete implementation of chloride reduction program. Address other potential sources of chloride as needed (e.g., wastewater).

a. Milestones are not provided for Salt Creek. A separate planning study is being completed by CMAP for the Salt Creek watershed.

8.7 Adaptive Management

To ensure management decisions are based on the most recent knowledge, the implementation plan follows the form of an adaptive and integrated management strategy and establishes milestones and benchmarks for evaluation of the implementation program. U.S. EPA (2008) recognizes that the processes involved in watershed assessment, planning, and management are iterative and that actions might not result in complete success during the first or second cycle. For this reason, it is important to remember that implementation will be an iterative process, relying upon adaptive management.

Figure 83. Adaptive management iterative process (USEPA 2008).

Adaptive management is a strategy to address natural resource management that involves a temporal sequence of decisions (or implementation actions), in which the best action at each decision point depends on the state of the managed system. As a structured iterative implementation process, adaptive management offers the flexibility for responsible parties to monitor implementation actions, determine the success of such actions and ultimately, base management decisions upon the measured results of completed implementation actions and the current state of the system. This process, depicted in Figure 83, enhances the understanding and estimation of predicted outcomes and ensures refinement of necessary activities to better guarantee desirable results. In this way, understanding of the resource can be enhanced over time, and management can be improved.

In addition to focusing future management decisions, with established assessment milestones and benchmarks, adaptive management can include a re-assessment of the TMDLs. Re-assessment of a TMDL is particularly relevant when completion of key studies, projects or programs result in data showing load reductions or the identification/quantification of alternative sources. Reopening/ reconsidering the TMDLs may include refinement or recalculation of load reductions and allocations.

The implementation phases, milestones, and benchmarks will guide the adaptive management process, helping to determine the type of monitoring and implementation tracking that will be necessary to gauge progress over time. Evaluation for adaptive management can include a variety of evaluation components to gain a comprehensive understanding of implementation progress. An implementation evaluation determines if non-structural and structural activities are put in place and maintained by implementation partners according to schedule; this is often referred to as an output evaluation. An outcome evaluation focuses on changes to behaviors and water quality as a result of implementation actions. This type of evaluation looks at changes in stakeholder behavior and awareness (i.e., non-structural BMP effectiveness), structural BMP performance, and changes to ambient water quality.

8.8 Public Education and Participation

Successful implementation will rely heavily on effective public education and outreach activities that will encourage participation and change behaviors. This section presents recommendations related to developing and implementing a coordinated watershed-wide public education and outreach program. This program will help to build the public support for implementation activities such as green infrastructure.

It is imperative to raise stakeholders' awareness about issues in the watershed and develop strategies to change stakeholders' behavior in a manner that will promote voluntary participation. Changes in awareness and behavior are surrogate indicators for longer-term changes in water quality. For example, strong public education and involvement in water quality improvement actives may encourage local governments and businesses to implement BMPs to meet the desires of citizens. Fortunately, several organizations within the

watershed are already conducting education and outreach on important water quality issues. While there exist multiple regional education and outreach effort, implementation of the TMDL may provide the opportunity for these entities to work together to ensure a consistent and overarching marketing campaign across the watershed. The following existing entities can provide the foundation for such a public education program:

- DuPage County Stormwater Management
- DuPage River Salt Creek Work Group
- The Conservation Foundation
- DuPage County Health Department
- Lower DuPage River Watershed Coalition
- Chicago Metropolitan Agency for Planning
- County Forest Preserve Districts
- Metropolitan Water Reclamation District of Greater Chicago
- School and Community Assistance for Recycling and Composting Education

Examples of existing education and outreach programs and opportunities are summarized below.

DuPage County Citizen Reporter Mobile App

The DuPage County Citizen Reporter App was launched in 2016 to facilitate a method for citizens and stakeholders with in DuPage County to share and collect observations of water quality and water resource concerns. The app uses a web-based GIS system to collect and store user inputted observations that can then be vetted through a voting system. The public can view all inputs and then vote if they agree or disagree with it. Users also have the option to upload photos and comment on other reports. The app provides DuPage County the possibility of continuous civic engagement and monitoring of water ways. More information can be found at: https://gis.dupageco.org/CitizenReporter/.

Conservation in our Community

The Conservation Foundation program, Conservation in our Community, aims for residents to "embrace the idea of conservation as a core community value that not only enhances the environment, but also conserves money". Currently, eight communities and one park district participate in the program. Suggested water related projects include:

- Volunteer groups to stencil stormwater drains
- Lunch and learns on water quality issues like stormwater runoff and erosion control for municipal employees
- Rain barrel sales

More information can be found at: <u>http://www.theconservationfoundation.org/page.php?PageID=42.</u>

Additional public outreach and education can include a variety of activities including newspaper articles, newsletters, radio spots, website content, workshops, demonstration projects and tours. A variety of activities can be undertaken in order to reach various target audiences.

Love Blue, Live Green Campaign

The Love Blue, Live Green is a DuPage County Stormwater Management social media campaign founded in 1988 to protect and enhance the quality of DuPage County waterways. It supports and hosts several educational events around the county that promote their mission. More information on the campaign can be found at their Facebook page: <u>https://www.facebook.com/LoveBlueDuPage/</u> and twitter: <u>https://twitter.com/lovebluedupage</u> sites.

School and Community Assistance for Recycling and Compositing Education (SCARCE)

School and Community Assistance for Recycling and Composting Education (SCARCE) is an environmental non-profit and resource center that provide educational programs for schools, businesses, municipalities, and more to provide environmental education. They host rain barrel workshops and provide a water quality flag certification for entities that are working to improve water quality in their area. More information can be found at: <u>https://www.scarce.org/about/</u>.

Adopt a Stream Programs

Various Adopt a Stream Programs exist throughout the watershed. For example, the DuPage County Adopt a Stream Program found here:

<u>https://www.dupageco.org/EDP/Stormwater_Management/Water_Quality/38387/</u>. These should be continued and expanded on impaired segments of river.

8.9 Monitoring

Monitoring is crucial to evaluating progress towards meeting water quality goals in the watershed and determining when adaptive management is needed. Monitoring is also needed to further refine source assessments so implementation activities can be focused in the most cost-effective way and to assess the effectiveness of source reduction strategies for attaining water quality standards and designated uses.

The ultimate measure of success will be documented changes in water quality, showing improvement over time (see Table 68 for progress benchmarks).

8.9.1 Water Quality Monitoring

Progress towards achieving water quality standards will be determined through ambient monitoring by Illinois EPA. The state conducts studies of ambient conditions across the state by evaluating watersheds on a rotating basis, collecting measurements of physical, chemical, and biological parameters. This ambient monitoring program will continue as the plan is implemented with a particular focus on impaired sites. Illinois EPA, in partnership with IDNR, additionally conducts Intensive Basin Surveys on a five-year rotational basis. These surveys collect water chemistry and biological (fish and macroinvertebrate) data, qualitative and quantitative instream habitat information, identify water quality conditions, and evaluate aquatic life use impairment. In addition to the monitoring conducted by Illinois EPA, the following organizations conduct water quality monitoring:

- DRSCW
- DuPage County and other NPDES permittees
- Lower DuPage River Watershed Coalition
- Forest Preserve of DuPage County through the Office of Natural Resources Aquatics Monitoring & Research Program
- Adopt-A-Stream program through DuPage County

Specific monitoring needs include sufficient data to assess fecal coliform impairments using both the single sample maximum and geometric mean water quality standards and to further evaluate the pathways of chloride in the watershed. Additional continuous dissolved oxygen monitoring and accompanying flow and water chemistry data are needed to further evaluate dissolved oxygen conditions in the Lower DuPage River watershed. Additional water quality sampling is also needed in most impaired segments to further define sources of pollutants.

8.9.2 BMP Effectiveness Monitoring

Multiple BMPs will be needed to address the water quality impairments in the DuPage River and Salt Creek watersheds. There are limited local data on the effectiveness of many BMPs; therefore, monitoring the results of programs and representative practices are critical. BMP monitoring can include quantitative

monitoring of physical components (e.g., water quality and flow), qualitative (i.e., visual) monitoring of physical components (e.g., vegetation), and monitoring of behaviors using pre and post surveys. A monitoring program could be put in place as both structural and nonstructural BMPs are implemented to (1) measure success and (2) identify changes that could be made to increase effectiveness. U.S. EPA (1999) describes water quality monitoring and reporting data that are useful for assessing the effectiveness of stormwater BMPs.

8.10 Technical and Financial Assistance

A significant portion of this implementation plan focuses on voluntary efforts as opposed to permit requirements. As a result, technical and financial assistance are essential to successful implementation over time. This section identifies sources of funding and technical assistance to implement the recommended implementation practices. This section also identifies the watershed partners who will likely play a role in implementation.

Partners

There are several partners that may provide technical or financial assistance to promote successful TMDL implementation and watershed management. Two key watershed groups are present: DRSCW and the Lower DuPage River Watershed Coalition. In addition to these two entities, other federal, state, and local partners include:

- Chicago Metropolitan Agency for Planning
- Conservation Foundation
- Chicago Wilderness
- School and Community Assistance for Recycling and Composting Education
- County Forest Preserve Districts
- Counties and Soil and Water Conservation Districts
- Illinois State Water Survey
- Illinois EPA
- Illinois Farm Bureau
- University of Illinois Extension
- Illinois Department of Agriculture
- Illinois Department of Natural Resources
- U.S. EPA Region 5
- NRCS
- Farm Service Agency

DuPage River Salt Creek Workgroup

The <u>DRSCW</u> was formed in 2005 and consists of local communities, publicly owned treatment works, and environmental organizations in the East and West Branch DuPage rivers and Salt Creek watersheds. Members work together to "better determine the stressors to the aquatic systems through a long term water quality monitoring program and develop and implement viable remediation projects" (DRSCW webpage). Permitted facilities that are members of DRSCW are required to address a series of special conditions within their NPDES permits that address water quality concerns and includes the completion of several water quality improvement projects as listed in Table 69. Special condition language is provided in Appendix G. The permit conditions require permittees to:

- Work with other DRSCW members to determine the most cost effective means of removing dissolve oxygen and other offensive condition impairments in the DRSCW watersheds
- Participate in the development of a watershed Chloride Reduction Program
- Submit a single annual progress report that is common among DRSCW permittees

- Develop a written Phosphorus Discharge Optimization Plan, complete a feasibility study to evaluate timeframe, and construction costs of reducing phosphorus levels, and achieve required P reductions in effluent in 10-11 years, depending on phosphorus removal technique (wastewater facilities only)
- Monitor wastewater effluent and influent for phosphorus and nitrogen in accordance to their permit and submitted to Illinois EPA (wastewater facilities only)
- Submit and implement a nutrient implementation plan that identifies phosphorus reduction strategies and their implementation schedule to meet applicable water quality criteria (wastewater facilities only)

Additionally, the DRSCW has dedicated significant resources to promote the reduction of chlorides in the watershed. In 2007, the <u>Chloride Usage Education and Reduction Program Study</u> was completed. The study compiled information on chloride usage within the watershed to calculate an estimated annual chloride load. Implementation of the plan has been ongoing. Activities have included chloride reduction workshops, developing educational materials and technical resources, and surveying municipalities on practices.

Lastly, the DRSCW has been active in dam removal or modification that results in increased dissolved oxygen and fish passage. Several studies have evaluated the effect of dams in the DuPage River watershed and determined that dams were contributing to ecological degradation (Hammer et al. 2003, Midwest Biological Institute 2014, 2016). Recently in the Salt Creek watershed, a conceptual plan for the Fullersburg Woods dam modification and stream restoration was completed, and the Oak Meadows Golf Course dam was removed and 1.5 miles of stream restoration was completed. In the East Branch, the Churchill Woods dam was modified to improve water quality and address fish passage and Fawell Dam is currently proposed for dam modification.

Lower DuPage River Watershed Coalition

Lower DuPage River Watershed Coalition was formed in "to provide a local, coordinated effort to address water resource concerns using a science based approach to identify water quality stressors and develop ecologically and economically sound approaches to restore stream health". Members include local communities, permitted facilities and local businesses interested in the Coalition's cause. In addition, membership dues fund a bioassessment monitoring program. In 2011, the Coalition completed a watershed-based plan for the Lower DuPage River to protect and manage watershed health (see Table 64) for more information). Members of the coalition have also chosen to have the DRSCW special conditions included in their NPDES permits.

Financial Assistance Programs

There are many existing financial assistance programs which may assist with funding implementation activities. Many involve cost sharing, and some may allow the local contribution of materials, land, and inkind services (such as construction and staff assistance) to cover a portion or the entire local share of the project. Several of these programs are presented in Table 71. In addition to these programs, partnerships between local governments can help to leverage funds. State and federal grant programs may also be available, depending on the nature of the implementation activity. A stormwater utility similar to those in place in the City of Wheaton and the Village of Downers Grove may also be used to generate local funds for stormwater programs. Table 71 was compiled from a review of existing funding opportunities as well as from existing watershed plans in the watershed.

Table 71. Potential funding sources

Funding Program	Type of Funding	Entity	Eligible Projects	Eligible Applicants	Available Funding	Website
Federal Programs				•		
Five Star Wetland and Urban Water Restoration Grant	Grant	U.S. EPA	On-the-ground wetland, riparian, in-stream and/or coastal habitat restoration, education and training activities through community outreach, participation and/or integration with K- 12 environmental curriculum. Projects that provide benefits to the community through ecological and environmental efforts, and partnerships.	Non-profits, state government agencies, local and municipal governments, Indian tribes, and educational institutions	\$10,000-\$40,000 per project	http://www.nfwf.org/fivestar/Pages/hom e.aspx
Wetland Program Development Grants	Grant	U.S. EPA	Projects that promote the understanding of water pollution through review and refinements of wetland programs. Cause and effects, reduction and prevention, and elimination of water pollution.	States, tribes, local governments, interstate associations, and intertribal consortia (Regional grants) Nonprofits, interstate associations and intertribal consortia (National grants)	\$20,000 to \$600,000/fiscal year	https://www.epa.gov/wetlands/wetland- program-development-grants
North American Wetlands Conservation Act (standard grant)	Grant through the North American Wetlands Conservation Act	USFWS	Wetlands conservation projects in the United States, Canada, and Mexico. Projects must provide long-term protection, restoration, and/or enhancement of wetlands and associated uplands habitats.	Non-profits, state government agencies, local and municipal governments, Indian tribes, and educational institutions	Since 1995 1,025 projects have been funded with a combined total of over \$850 million grant dollars. Requires a 1-1 partner contribution	https://www.fws.gov/birds/grants/north- american-wetland-conservation- act/standard-grants/united-states.php
North American Wetlands Conservation Act (small grant)	Grant through the North American Wetlands Conservation Act	USFWS	Wetlands conservation projects in the United States, Canada, and Mexico. Grant requests must not exceed \$100,000.	Non-profits, state government agencies, local and municipal governments, Indian tribes, and educational institutions	Since 1996, 750 projects have been funded with a combined total of \$43.2 million grant dollars Requires a 1-1 partner contribution	https://www.fws.gov/birds/grants/north- american-wetland-conservation- act/small-grants.php
Environmental Quality Incentive Program (EQIP)	Cost-share through contract (usually 3 years)	NRCS	Approved conservation practices that are constructed according to NRCS.	Farmers in livestock, agricultural, or forest production who utilize approved conservation practices	Up to 75% of project cost	https://www.nrcs.usda.gov/wps/portal/n rcs/main/il/programs/financial/eqip/
National and State Conservation Innovation Grants	EQIP funded grants	NRCS	Innovative problem-solving projects that boost production on farms, ranches, and private forests that improve water quality, soil health, and wildlife habitat.	Non-federal governmental or nongovernmental organizations, American Indian Tribes, or individuals. Producers involved in CIG funded projects must be EQIP eligible.	More than \$22.6 million was awarded to 33 projects in 2017 Grantees much match funds	https://www.nrcs.usda.gov/wps/portal/n rcs/main/national/programs/financial/ci g/
Environmental Education Grants Program	Grant	U.S. EPA	Environmental education programs that promote environmental awareness and stewardship and help provide people with the skills to take responsible actions to protect the environment. This program is currently waiting on the Fiscal Year 2017 budge before issuing a request for proposals.	 Local education agencies State education or environmental agencies Colleges or universities Non-profit organizations 501(c)(3) Noncommercial educational broadcasting entities Tribal education agencies (including schools and community colleges controlled by an Indian tribe, band, or nation) 	In 2015, 35 projects in the county were funded for a total of \$3,306,594	https://www.epa.gov/education/environ mental-education-ee-grants
State/Federal Partnerships		•	•	· · · · ·		
Nonpoint Source Management Program (319)	Grant	U.S.EPA/ IEPA	 Priority given to projects that implement cost-effective corrective and preventative BMPs on a watershed scale. Also available for BMPs on a non-watershed scale and the development of information/education nonpoint source pollution control programs. Projects that meet requirements of a NPDES permit are not eligible for 319 funding. 	Units of government and other organizations	Approximately \$3,000,000 is available per year, awarded amongst approximately 15 projects. Provides up to 60% project cost share	http://www.epa.illinois.gov/topics/water -quality/watershed- management/nonpoint- sources/grants/index Supplemental guidance on 319 funding for urban BMPS: http://www.epa.state.il.us/water/waters hed/publications/nps-pollution/urban-

Funding Program	Type of Funding	Entity	Eligible Projects	Eligible Applicants	Available Funding	Website
Clean Water State Revolving Fund	Low interest loans, purchase of debt or refinance, subsidization	IEPA	Nonpoint source pollution control. Green infrastructure projects, construction of municipal wastewater facilities and decentralized wastewater treatment systems, watershed pilot projects, stormwater management, technical assistance (qualified nonprofit organizations only).	Corporations, partnerships, governmental entities, tribal governments, state infrastructure financing authorities	Varies	https://www.epa.gov/cwsrf
Healthy Forest Reserve Program	Easements, 30- year contracts, 10 year contracts	USDA	Projects that restore, enhance and protect forestland reserves on private land to measurably increase the recovery of threatened or endangered species, improve biological diversity, or increase carbon storage.	Private landowners	 10-year restoration cost-share agreement: up to 50% of average cost of approved conservation practices 30-year easement: up to 75% of the easement value of the enrolled land plus 75% of the average cost of the approved conservation practices 30-year contract on acreage owned by Indian Tribes Permanent easements: up to 100% of the easement value of the enrolled land plus 100% of the average cost of the approved conservation practices 	https://www.nrcs.usda.gov/wps/portal/n rcs/main/national/programs/easements /forests/
Healthy Watersheds Consortium Grant	Grant	EPA, NRCS and U.S. Endowment for Forestry and Communities	 "Healthy watershed" program development projects that aim to preserve and protect natural areas, or local demonstration/trainings Conservation easements are <i>not</i> eligible Grants awarded are generally within three categories: Short term funding to leverage larger financing for targeted watershed protection Funds to help build the capacity of local organizations for sustainable, long term watershed protection New replicable techniques or approaches that advance the state of practice for watershed protection. 	Consortiums or "one entity who is linked with or in a collaborative partnership with other groups or organizations having similar healthy watersheds protection goals"	\$50,000-150,000 per project	https://www.epa.gov/hwp/healthy- watersheds-consortium-grants-hwcg
Partners for Fish and Wildlife Program	Technical and financial support	USFWS	Collaborations and partnerships with private landowners to improve fish and wildlife habitat on their lands. Voluntary, community-based stewardship for fish and wildlife conservation.	Private landowners	Varies per project/partners	https://www.fws.gov/midwest/partners/i ndex.html
State Programs		•				
Streambank Stabilization and Restoration Program	Grant	Illinois Department of Agriculture	Labor, equipment, and materials for effective streambank stabilization demonstration sites that use inexpensive vegetative and bio-engineering techniques.	This program is currently not funded but may be reinstated in the future.	This program is currently not funded but may be reinstated in the future.	https://www.agr.state.il.us/conservation /.
Open Space Lands Acquisition and Development Grant/Land and Water Conservation Fund Grant	Grant	IDNR	Acquisition and/or development of land for public parks and open space by Illinois governments.	Local governments	Up to \$750,000 for acquisition projects and \$400,000 for development/renovation projects. Funding up to 50% of project cost	https://www.dnr.illinois.gov/aeg/pages/ openspacelandsaquisitiondevelopment -grant.aspx
Illinois Buffer Partnership	Cost share, on site assistance from Trees Forever (Iowa) staff, project signs and field days	Illinois Buffer Partnership	Eligible projects include: Installation of streamside buffer plantings on projects including riparian buffers, livestock buffers, streambank stabilization projects, wetland development, pollinator habitat, rain gardens, and agroforestry projects.		Reimbursed up to \$2,000 for 50% of the expenses remaining after other grant programs are applied	<u>http://www.treesforever.org/Illinois Buf</u> fer_Partnership.

Funding Program	Type of Funding	Entity	Eligible Projects	Eligible Applicants	Available Funding	Website
Local/Regional Programs						
CMAP Local Technical Assistance Program	In-kind technical assistance	СМАР	Recommended activities in CMAP's Go To 2040 plan.	Chicago Area governments, nonprofits, and intergovernmental organizations	NA	http://www.cmap.illinois.gov/programs- and-resources/Ita
Water Quality Improvement Grant Program	Grant	DCSM	Eligible projects include: Stream bank stabilization involving bioengineering practices, in-stream habitat improvement, pond restoration, channel rehabilitation, riparian buffer rehabilitation, wetland creation and/or restoration, and green infrastructure to reduce or filter stormwater runoff that provide a regional water quality benefit.	Any organization or individual within DuPage County, IL	Up to 25% of construction costs for the portions of projects that provide water quality benefits not otherwise required Up to 25% of the maintenance and monitoring costs are eligible for reimbursement	https://www.dupageco.org/EDP/Storm water_Management/Water_Quality/13 12/

September 2019

8.11 Reasonable Assurance

U.S. EPA requires that a TMDL provide reasonable assurance that the required load reductions will be achieved and water quality will be restored. Point source dischargers and MS4s contribute the majority of pollutant loading in the watershed. Illinois EPA will assure implementation of TMDLs through its NPDES and regulated stormwater programs. For nonpoint source control in the watershed, the implementation plan provides information that supports reasonable assurance that practices will be implemented.

The DRSCW and the Lower DuPage River Watershed Coalition are key partners who have an active role in watershed management and water quality improvement in the watershed. These entities will continue to provide leadership, with support from various other entities. These partners and their work in the watershed are summarized in Section 8.10.

Major regulatory examples of water quality improvement actions include ordinances such as the Will County watershed management ordinance, the DuPage County countywide stormwater and flood plain ordinance, the DRSCW salt reduction program implementation, and local pet waste ordinances such as the City of Geneva's, among others (see Section 8.4.1 for more details). On a state level, Illinois is developing a nutrient loss reduction strategy (<u>https://www2.illinois.gov/epa/topics/water-quality/watershed-management/excess-nutrients/Pages/nutrient-loss-reduction-strategy.aspx</u>) to address nutrient loading to waterways. The strategy promotes BMPs to reduce nutrient levels that have the co-benefit of increasing dissolved oxygen levels instream.

Examples of on-going activities in the watershed being led by the DRSCW include practices and strategies with co-benefits to impaired streams are also seen throughout the watershed. The recently completed dam removal and stream restoration at the Oak Meadows golf course is one example of a practice with co-benefits to aquatic habitat and other factors influencing dissolved oxygen. The project removed Oak Meadow dam, reconnected the river segment to its floodplain, established 25 acres of new wetlands and 43 acres of riparian habitat. Post project monitoring conducted in 2017 show an increase in habitat scores at all sites noted improvements in substrate, riparian, pool and riffle scores. In addition to improved habitat, dissolved oxygen scores data collected post project would suggest a modest improvement in the dissolved oxygen regime with a probable improvement in mean dissolved oxygen (DRSCW 2018). Numerous other existing and on-going planning activities exist in the watershed to improve water quality as summarized in Section 8.1.3 and Table 64.

Specific to the GB-16 Dissolved Oxygen TMDL, two TMDL scenarios are provided in Section 7.2.2. Under both scenarios, there are changes to permitted point source discharges (CBOD₅ and dissolved oxygen). These changes will be addressed via the NPDES permit; Illinois EPA has provided language in Section 7.2.2 that describes the Agency's approach to setting effluent limits associated with this TMDL. In addition, reducing the SOD rate and coverage and reducing total phosphorus loads is needed. As described in Section 8.5.3, a 19% reduction in total phosphorus is needed in the contributing watershed to GB-16 under both scenarios. Achieving this reduction will be the result of continued implementation of NPDES permits and targeted management practices in the watershed to reduce watershed loads.

The DRSCW, in addition to DuPage County Stormwater and other local entities, have a successful history of water quality implementation in this part of the watershed. Phosphorus reductions should result in lower SOD rates and coverage along GB-16, the extent of which is difficult to predict. The implementation plan relies on adaptive management over time and sets progress benchmarks and an implementation schedule on which to track improvements.

In addition to the above activities, educational efforts and cost-share programs will be relied upon to increase participation to levels needed to protect water quality. Existing educational programs are summarized in Section 8.8 and include adopt-a-stream programs, water quality improvement campaigns, and citizen monitoring programs. Technical and financial assistance, as summarized in Section 8.10, provide the resources needed to improve water quality and meet watershed goals.

iv

Executive Summary

As required by Section 303(d) of the Clean Water Act (CWA), the Illinois Environmental Protection Agency (Illinois EPA) is required to identify and list all state waters that fail to meet water quality standards. This list is referred to as the 303(d) list and is revisited every two years to either remove those waters that have attained their designated uses, or to include additional waters not previously deemed impaired. Waterbodies included on the 303(d) list require Total Maximum Daily Load (TMDL) development.

A TMDL is an estimation of the maximum amount of a pollutant that a waterbody can receive and still meet water quality standards. It assesses contributing point and nonpoint sources to identify pollution reductions necessary for designated use attainment. A TMDL identifies the source of impairment and provides reduction estimates to meet water quality standards. Pollutant reductions are then allocated to contributing sources, thus triggering the need for pollution control and increased management responsibilities amongst sources in the watershed.

For the DuPage River/Salt Creek watershed 17 impaired waterbodies were identified for TMDL development. The DuPage River/Salt Creek Watershed (Figure 2-1) is located in northeastern Illinois and originates from two branches in the northern most part of the watershed. The West Branch DuPage River is approximately 35 miles long and the East Branch DuPage River is approximately 25 miles long. Both branches flow south until they meet around Bolingbrook, creating the main branch of the DuPage River. The DuPage River flows approximately 30 additional miles before the confluence with the Des Plaines River near the town of Channahon, IL. Two tributaries and a lake will be included in the TMDL. Spring Brook is a tributary of the West Branch DuPage River and flows southwest for approximately 5.5 miles before the confluence with the West Branch of the DuPage River. Addison Creek is a tributary of Salt Creek and flows southeast for approximately 10.5 miles before the confluence with Salt Creek. Churchill Lagoon was formed by damming the East Branch DuPage River.

The only waterbody classification applicable to the DuPage River/Salt Creek watershed is the General Use classification which includes designated uses such as aquatic life, aesthetic quality, fish consumption and primary contact recreation uses. The identified impairments include total phosphorus, fecal coliform, pH, dissolved oxygen, silver, manganese, and chloride. The water quality standard criteria identified for these impairments provide an explicit assessment as to whether or not these waterbodies are in compliance.

Available data used for assessing these waterbodies originated from numerous water quality stations within the DuPage River/Salt Creek watershed. Data were obtained from both legacy and modernized USEPA Storage and Retrieval (STORET) databases, Metropolitan Water Reclamation District of Greater Chicago (MWRDGC) data, Sierra Club, Wheaton Sanitary District, DuPage River Salt Creek Workgroup and Illinois EPA database data. Data relevant to impairments were compiled for each impaired waterbody and summary statistics were calculated to further characterize each pollutant.

Various models were recommended for TMDL development, the level of which was primarily based on the complexity of the system and the availability of data. Simple spreadsheet models were recommended for DO TMDLs and the ENSR Lake Response Model (ENSR LRM) was recommended to analyze total phosphorus impairment. Load duration curves were recommended for fecal coliform and metals analyses and could also be used to estimate BOD loading for the DO TMDL. If the system requires a more complex DO model for creek simulation, then QUAL2K could be used. QUAL2K was recommended for the pH TMDL, but is capable of simulating in-stream DO concentrations.

1.0 Introduction

This Stage 1 Total Maximum Daily Load (TMDL) report is presented as partial fulfillment by the Illinois Environmental Protection Agency (Illinois EPA) and the United States Environmental Protection Agency (US EPA) in the development of TMDLs, as part of that state's Clean Water Act (CWA) Section 303(d) compliance. The purpose of the project is to develop TMDLs for seventeen designated waterbodies in the DuPage River and Salt Creek watershed in northeastern Illinois.

Section 303(d) of the CWA and U.S. EPA's Water Quality Planning Regulations (40 CFR Part 130) require states to develop TMDLs for impaired waterbodies that are not meeting designated uses or water quality standards. A TMDL is a calculation of the maximum amount of pollutants that a waterbody can receive and still meet the water quality standards necessary to protect the designated beneficial use (or uses) for that waterbody. The TMDL process establishes the allowable loadings of pollutants for a waterbody based on the relationship between pollutant sources and water quality conditions, so that states and local communities can establish water quality based controls to reduce pollutants from both point and nonpoint sources and restore and maintain the quality of their water resources.

Water is an essential resource for the inhabitants of the Earth and protecting this resource is the goal for many across the globe. United States policies and regulations, such as the CWA, were created and are implemented to help maintain the quality of our water resources in the United States. The U.S. EPA, via the CWA, charged each state with developing water quality standards (WQS). These WQS are laws or regulations that states authorize to protect and/or enhance water quality, to ensure that a waterbody's designated use (or uses) is (are) not compromised by poor water quality and to protect public health and welfare. In general, WQS consist of three elements:

- The designated beneficial use (e.g., recreation, protection of aquatic life, aesthetic quality, and public and food processing water supply) of a waterbody or segment of a waterbody,
- The water quality criteria necessary to support the designated beneficial use of a waterbody or segment of a waterbody, and
- An anti-degradation policy, so that water quality improvements are conserved, maintained and protected.

The Illinois Pollution Control Board (IPCB) established its WQS and includes it in Title 35: Environmental Protection, Subtitle C: Water Pollution, Chapter 1: Pollution Control Board, Part 302: Water Quality Standards. Every two years the Illinois EPA submits the Illinois Integrated Water Quality Report and Section 303(d) List. This report documents surface and groundwater conditions throughout the state. The 303(d) List portion of this report identifies impaired waterbodies, grouped by watershed, and identifies suspected sources of impairment. These waters are prioritized for TMDL development into high, medium, and low categories based on designated use and pollution severity and are then targeted for TMDL development. Non-pollutant causes of impairment, such as habitat degradation and aquatic algae, are not addressed under the TMDL, but are address by programs such under the 319 program and other nonpoint source grant programs. Some non-pollutants may be addressed by reducing pollutants for which a TMDL is developed. For example, some implementation activities to reduce phosphorus can also reduce excessive algae and improve aquatic habitat.

A TMDL is a calculation of the maximum load a waterbody can be receive without exceeding water quality standards or result in non attainment of a designated use. A watershed's TMDL report consists of data analysis to quantitatively assess water quality, documentation of waterbodies or segments of waterbodies that are impaired, and identification of potential contributing sources to impairment. Based on these data, the amount and type of load reduction that is needed to bring water quality into compliance is calculated. The TMDL report provides the scientific basis for states and local communities to establish water quality-based

controls to reduce pollutant loads from both point (i.e., wasteload allocations) and non-point sources (i.e., load allocations).

Illinois EPA uses a three-stage approach to develop TMDLs for a watershed:

- **Stage 1** Watershed characterization, historical dataset evaluation, data analysis, methodology selection, data gap identification;
- Stage 2 Data collection to fill in data gaps, if necessary; and
- Stage 3 Model calibration, TMDL scenarios, and implementation plans.

The purpose of Stage 1 is to characterize the watershed background; verify impairments in the listed waterbody by comparing observed data with water quality standards or appropriate targets; evaluate spatial and temporal water quality variation; provide a preliminary assessment of sources contributing to impairments; and describe potential TMDL development approaches. If available water quality data collected for the watershed are deemed sufficient by Illinois EPA, Stage 2 may be omitted and Stage 3 will be completed. If sufficient water quality data or supporting information are lacking for an impaired waterbody, then Stage 2 is required and field samplings will be conducted in order to obtain necessary data to complete Stage 3. Stage 3 includes model development, allocations and reductions needed for waterbody improvement and implementation actions for local stakeholders.

This report documents Stage 1 in the Illinois EPA approach for TMDL development. The report is organized into six main sections. Section 1.0 discusses the definition of TMDLs and targeted impaired waterbodies in the DuPage River and Salt Creek watershed, for which TMDLs will be developed. Section 2.0 describes the characteristics of the watershed, and Section 3.0 briefly discusses the process of public participation and involvement. Section 4.0 describes the applicable water quality standards and water quality assessment. Section 5.0 presents the assessment and analysis of available water quality data. Section 6.0 discusses the methodology selection for the TMDL development, the data gaps, and provides recommendations for additional data collection, if necessary.

1.1 Definition of a Total Maximum Daily Load (TMDL)

According to the 40 CFR Part 130.2, the TMDL (the maximum load a waterbody can be receive without exceeding water quality standards or result in non attainment of a designated use) for a waterbody is equal to the sum of the individual loads from point sources (i.e., wasteload allocations or WLAs), and load allocations (LAs) from nonpoint sources (including natural background conditions). Section 303(d) of the CWA also states that the TMDL must be established at a level necessary to implement the applicable water quality standards with seasonal variations and a margin of safety (MOS) which takes into account any lack of knowledge concerning the relationship between effluent limitations and water quality. In equation form, a TMDL may be expressed as follows:

TMDL = WLA + LA + MOS

where:

WLA = Waste Load Allocation (i.e., loadings from point sources);

LA = Load Allocation (i.e., loadings from nonpoint sources including natural background); and MOS = Margin of Safety.

TMDLs can be expressed in terms of either mass per time, toxicity or other appropriate measures [40 CFR, Part 130.2 (i)]. US EPA recommends that all TMDLs and associated LA and WLAs be expressed in terms of daily increments but may include alternative non-daily expression of pollutant loads to facilitate implementation of the applicable water quality standard. TMDLs also shall take into account the seasonal variability of pollutant loading and hydrology to ensure water quality standards are met in all seasons and during all hydrologic

conditions. Though not required by CWA, Illinois EPA requires that an implementation plan be developed for each watershed, which may be used as a guideline for local stakeholders to restore water quality. This implementation plan will include recommendations for implementing best management practices (BMPs), cost estimates, institutional needs to implement BMPs and controls throughout the watershed, and time frame for completion of implementation activities.

The MOS accounts for the lack of knowledge or uncertainty concerning the true relationship between loading and attainment of water quality standards. This uncertainty is often a product of data gaps, either temporally or spatially, in the measurement of water quality. The MOS should be proportional to the anticipated level of uncertainty; the higher the uncertainty, the greater the MOS. The MOS is generally based on a qualitative assessment of the relative amount of uncertainty as a matter of best professional judgment (BPJ). The MOS can be either explicit or implicit. If an explicit MOS is used, a portion of the total allowable loading is allocated to the MOS. If the MOS is implicit, a specific value is not assigned to the MOS, but is already factored in during the TMDL development process. Use of an implicit MOS is appropriate when assumptions used to develop the TMDL are believed to be so conservative that they sufficiently account for the MOS.

1.2 Targeted Waterbodies for TMDL Development

In May 2008, Illinois EPA prepared a draft Illinois Integrated Water Quality Report and Section 303(d) List-2008 (commonly referred to as the 303(d) List) to fulfill the requirement of Section 305(b), 303(d) and 314 of the CWA (Illinois EPA, 2008). Under US EPA's review and approval, the report presents a detailed water quality assessment process and results for streams and lakes in the State of Illinois. The water quality assessments are based on biological, physicochemical, physical habitat, and toxicity data. Each waterbody has one or more of designated uses which may include aquatic life, aesthetic quality, indigenous aquatic life (for specific Chicago-area waterbodies), primary contact (swimming), secondary contact (recreation), public and food processing water supply, and fish consumption. The degree of support (attainment) of a designated use in a waterbody (or segment) is assessed as Fully Supporting (good), Not Supporting (fair), or Not Supporting (poor). Waters in which at least one applicable use is not fully supported is designated as "impaired." Potential causes and sources of impairment are also identified for these waters. The 303(d) List is prioritized on a watershed basis based on the requirements of 40 CFR Part 130.7(b)(4). Watershed boundaries are based on United States Geological Survey (USGS) ten-digit hydrologic units, to provide the state with the ability to address watershed issues at a manageable level and document improvements to a watershed's health (Illinois EPA, 2008). TMDL development is also conducted on a watershed basis so that the impaired waters upstream of an individual segment may be addressed at the same time.

Sixteen river segments and one lake segment are identified as impaired and selected for TMDL development in the DuPage River/Salt Creek Watershed (Illinois EPA, 2008). Table 1-1 summarizes these waterbodies, designated uses, and impairments identified by the Illinois EPA 2008 Integrated Report (303(d) List and Stream Assessment Report). The designated uses for these waterbodies include aesthetic quality, primary contact recreation (swimming), aquatic life, and fish consumption. The identified impairments include total phosphorus, fecal coliform, pH, dissolved oxygen, silver, manganese, and chloride. Fecal coliform is the predominant impairment within the watershed. The WQS provide numerical criteria to measure compliance for each of these water quality variables. DO is considered a non-pollutant by Illinois EPA. For dissolved oxygen impairments, the dissolved oxygen parameter itself will not be calculated as a TMDL, but will be addressed through a different, contributory parameter with a numerical WQS. This contributory parameter will be identified in the Stage 3 TMDL Report. For example, if a 50-acre lake suffers from low DO due to excessive algal densities which is related to elevated phosphorus concentrations, the Illinois EPA will develop a phosphorus TMDL for this waterbody. A TMDL will not be developed for waterbodies listed as impaired based on non-numerical WQSs (e.g., excessive algae) or statistical guidelines (e.g., total suspended solids). For other causes such as total suspended solids, the TMDL implementation plan can potentially address the impairment by reducing other TMDL parameters that are associated with this impairment. For example, a TMDL done for phosphorus in lakes will recommend BMPs in the implementation plan that when put in place

could reduce siltation/sedimentation and total suspended solid impairments. Reduction of phosphorus in lakes could also reduce the impairment of excessive aquatic algae and plants.

Table 1-1: Illinois 2008 Integrated Report (303(d) and Waterbody Assessment) Information for DuPage River and Salt Creek Watershed

Waterbody ID	Waterbody Name	Water Size (Miles/ Acres)	Designated Use	Impairment
IL_GB-01	L_GB-01 DuPage River 8		Aquatic Life	Aquatic Plants (Macrophytes), Other Flow Regime Alteration, Phosphorus, Sedimentation/Siltation, Silver (1)

			Aquatic Life	Aldrin, Aquatic Algae, Phosphorus (Total) (1)(3) , Silver, Total Suspended Solids

(1) These parameters have numeric standards and will have TMDL allocations.

(2) These parameters are or will be addressed by implementation activities within the watershed based on previous TMDL studies.

(3) At the time of this report, dam removal is being discussed for this lagoon and the numeric standard may not be applicable to this waterbody. More information will be available in the Stage 3 TMDL Report.

*The source causing impairment is believed to originate solely from point sources. The point source will be required to meet the water quality standard at the point of discharge. The Illinois EPA, based on the information available, believes that the compliance with the WQS will be achieved after all point source dischargers have installed the appropriate controls. A TMDL will not be prepared for this pollutant at this time, but will assess the waterbody again after the appropriate point source controls have been operational.

Table 1-2: Waterbodies targeted for TMDL development in the DuPage River and Salt Creek Watershed and potential sources of impairment

Waterbody ID	Waterbody Name	Impairment	Potential Source(s)
IL_GB-01	DuPage River	Silver	Urban Runoff/Storm Sewers
IL_GB-11	DuPage River	Chloride	Municipal Point Source Discharges, Urban Runoff/Storm Sewers
		Fecal Coliform	Source Unknown
IL_GB-16 DuPage Riv		Dissolved Oxygen	Impacts from Hydrostructure Flow Regulation/modification, Urban Runoff/ Storm Sewers
		Fecal Coliform	Municipal Point Source Discharges, Urban Runoff/Storm Sewers, Site Clearance (Land Development or Redevelopment), Source Unknown
IL_GBK-05	West Branch DuPage River	Dissolved Oxygen	Impacts from Hydrostructure Flow Regulation/modification, Municipal Point Source Discharges, Urban Runoff/ Storm Sewers
		Fecal Coliform	Source Unknown
IL_GBK-09	West Branch DuPage River	рН	Source Unknown
		Dissolved Oxygen	Municipal Point Source Discharges, Urban Runoff/Storm Sewers
		Silver	Urban Runoff/Storm Sewers

		Fecal Coliform	Urban Runoff/Storm Sewers
IL_GL-19	Salt Creek	рН	Urban Runoff/Storm Sewers
		Fecal Coliform	CSOs, Urban Runoff/Storm Sewers
IL_GLA-02	Addison Creek	Fecal Coliform	Combined Sewer Overflows, Urban Runoff/Storm Sewers
IL_RGG	Churchill Lagoon	Phosphorus (Total)(1)	Municipal Point Source Discharges, Runoff from Forest/Grassland/Parkland, Urban Runoff/Storm Sewers

(1) At the time of this report, dam removal is being discussed for this lagoon and the numeric standard may not be applicable to this waterbody. More information will be available in the Stage 3 TMDL Report

1.3 Previous TMDL Development in Watersheds

Previous TMDL Reports have been developed in these watersheds. See Tables 1.3 to 1.5 for information on the parameters that the TMDLs addressed.

The development of the West Branch DuPage River, East Branch DuPage River and Salt Creek TMDLs began in 2000. The West Branch DuPage River was approved by USEPA in May 2004 and the other two were approved in September of 2004. As a result of these TMDL processes many stakeholders in the watershed organized the DuPage River Salt Creek Workgroup (DRSCW) that consists of community groups, municipalities, and environmental organizations. This group was formed to better determine the stressors in the aquatic system through a long term quality monitoring program and develop and implement viable implementation projects to accurately address the stressors. For more information on this group, please visit their website at http://www.drscw.org/about_us.htm. More information on watershed groups can be found in Section 3.0. The implementation plan, which is done in Stage 3 of TMDL development, will include information on projects completed or ongoing in the watershed.

Waterbody ID	Waterbody Name	Pollutant(s)

2.0 Watershed Characterization

As part of the Stage I report, relevant geologic and hydrologic characteristics and general information are obtained for the watershed of interest. This section describes the general characteristics of the DuPage River/Salt Creek watershed including location (Section 2.1), topography (Section 2.2), land use (Section 2.3), soil information (Section 2.4), population (Section 2.5), climate and precipitation (Section 2.6) and hydrology (Section 2.7).

2.1 Watershed Location

A watershed is a geographic area that shares a hydrologic connection - all the water within that area drains to a common waterway. Water movement can be influenced by topography, soil composition and water recharge (i.e. precipitation, snow melt, groundwater) ("What is a Watershed", 2007). Watersheds are important because pollution at the water's source may impact water quality in all down-gradient areas including its convergence with a common waterway. Understanding the watershed is an essential step in the TMDL process – an essential tool in maintaining water quality standards within Illinois.

The DuPage River/Salt Creek Watershed (Figure 2-1) is located in northeastern Illinois and is approximately 520 mi² (332,600 acres). The watershed includes the DuPage River (USGS HUC 0712000408) and Salt Creek (USGS HUC 0712000404) which are within Cook, Kendal, Will, Gundy, and DuPage counties. The DuPage River originates from two branches in the northern most part of the watershed. The West Branch DuPage River and East Branch DuPage River are approximately 35 miles and 25 miles long, respectively. Both branches flow south until they meet around Bolingbrook, creating the main branch of the DuPage River. The DuPage River approximately runs an additional 30 miles before the confluence with the Des Plaines River near the town of Channahon, IL. Spring Brook, another tributary to the DuPage River, flows southwest for approximately 5.5 miles before the confluence with the West Branch DuPage River.

Salt Creek and Addison Creek are 40 miles and 6.5 miles long, respectively, prior to their confluence approximately 3 miles upstream of the Des Plaines River. The Des Plaines River flows southwest, and after its confluence with the DuPage River, joins the Illinois River, a major tributary of the Mississippi River. Figure 2-2 displays the waterbodies targeted for TMDL development.

Figure 2-2: DuPage River/Salt Creek Watershed Waterbodies for TMDL Development

2.2 Topography

Topography influences soil types, precipitation, and subsequently, watershed hydrology and pollutant loading. For the DuPage/Salt Creek watershed, a USGS 30-meter resolution digital elevation model (DEM) was obtained from the Illinois Natural Resources Geospatial Data Clearinghouse to characterize the topography. The DEM was then cropped to the extents of the Salt Creek and DuPage River watersheds combined, as provided by the Illinois EPA, and analyzed. Figure 2-3 displays elevations throughout the DuPage River/Salt Creek watershed. In general, the watershed starts at a higher elevation in the north and west and grades down to a lower elevation in the south or east toward the Des Plaines River, resulting in overall surface water flow from northwest to southeast. There is an increased elevation ridge that separates the Salt Creek and DuPage River watersheds. The percent change in elevation across the DuPage River/Salt Creek Watershed is approximately 93% and ranges from 974 feet to 505 feet.

The elevation at the Salt Creek headwaters is 895 feet and flow approximately 43 miles before it enters the Des Plaines River (elevation of 607 feet), resulting in a stream gradient of 6.72 feet per mile (0.0013 slope). The elevation at the DuPage River headwaters is 974 feet and flow into the Des Plaines River 63 miles downstream (elevation of 505 feet). The resulting stream gradient is 7.44 feet per mile (0.0014 slopes).

2.3 Land Use

Land use is as dynamic as the water moving throughout a watershed. It is constantly changing and has a large impact on the quality of a watershed. Land use data for the watershed were extracted from the Illinois Gap Analysis Project (IL-GAP) Land Cover data layer. IL-GAP was started at the Illinois Natural History Survey (INHS) in 1996, and the land cover layer was the first component of the project. The IL-GAP Land Cover data layer is a product of the Illinois Interagency Landscape Classification Project (IILCP), an initiative to produce statewide land cover information on a recurring basis cooperatively managed by the United States Department of Agriculture National Agricultural Statistics Service (NASS), the Illinois Department of Agriculture (IDA), and the Illinois Department of Natural Resources (IDNR). The land cover data were generated using 30-meter grid resolution satellite imagery taken during 1999 and 2000. The IL-GAP Land Cover data layer contains 23 land cover categories, including detailed classification in the vegetated areas of Illinois.

Tables 2-1 and 2-2 summarize the land use for the DuPage River and Salt Creek watersheds, respectively. Figure 2-4 shows land use and land cover in the DuPage River/Salt Creek Watershed and indicates that urban lands are dominant in both sub-watersheds, accounting for 65.0% of the total area in the DuPage River watershed and 84.8% in the Salt Creek watershed. In the DuPage River watershed, urban open space is the predominant land use (26.7% of the total land cover), while medium density urban built-up is the predominant land use (26.7% of the total land cover), while medium density urban built-up is the predominant land use in the Salt Creek watershed (37.0% of total land cover). Agricultural land accounts for 21.2% of land cover in the DuPage watershed, but only 0.3% in the Salt Creek watershed. Of the agricultural land in the DuPage watershed, soybeans and corn contribute the most to the agricultural land cover (9.1% and 8.1%, respectively). The other land uses are very similar between the two watersheds. In the DuPage River watershed, forested land accounts for 9.5% of the area, while wetlands (1.9%), surface water (1.8%) and barren and exposed land (0.6%) account for the remaining land uses. In the Salt Creek watershed, forested land makes up 11.9% of the area, and surface water (2.0%), wetland (1.0%) and barren and exposed land (0.03%) are the other existing land uses.

IL Gap Classification	Acreage	Percent	Summarized Acreage	Summarized Percentage
Urban and Built-up Land: Urban Open Space	64115.6	26.7%

2.4 Soils

Soils data and Geographic Information Systems (GIS) files from the Natural Resources Conservation Service (NRCS) were used to characterize soils in the DuPage River and Salt Creek watershed. General soils data and map unit delineations for the country are provided as part of the Soil Survey Geographic (SSURGO) database. Field mapping methods using national standards are used to construct the soil maps in the SSURGO database. Mapping scales generally range from 1:12,000 to 1:63,360; SSURGO is the most detailed level of soil mapping prepared by the NRCS. A map unit is composed of several soil series having similar properties. Identification fields in the GIS coverage can be linked to a database that provides information on chemical and physical soil characteristics. The SSURGO database contains many soil characteristics associated with each map unit.

The SSURGO data were analyzed based on drainage class (Figure 2-6), hydrologic group (Figure 2-5) and Kfactor (Figure 2-7), a coefficient of the Universal Soil Loss Equation (USLE). The drainage class, as stated in the SSURGO database is, "The natural drainage condition of the soil [which] refers to the frequency and duration of wet periods" (Soil Survey Staff, "Table Column Descriptions"). Poorly drained soils can be found in areas where there is frequent flooding such as land adjacent to lakes and streams. However, some excessively drained areas can be found interspersed around the lakes. Excessively drained areas may in part be caused by anthropogenic sources, such as construction of residential and paved areas near the lakes. It may also be a part of the natural geology, with localized areas prone to excessive drainage. The majority of the eastern border of the watershed is moderately well drained.

Soils that remain saturated or inundated for a sufficient length of time become hydric through a series of chemical, physical and biological processes. Once a soil takes on hydric characteristics, it retains those characteristics even after the soil is drained. Therefore hydric soils are the best indicator of what is or once was a wetland (SMC 2007). Wetlands help control flooding by retaining water when it rains and then releasing it slowly back into lakes and streams. The longer a soil is inundated the more likely it is that it will become hydric.

The hydrologic soil group classification identifies soil groups with similar infiltration and runoff characteristics during periods of prolonged wetting. Typically, clay soils that are poorly drained have lower infiltration rates, while well-drained sandy soils have the greatest infiltration rates. USDA has defined four hydrologic groups (A, B, C, or D) for soils. Type A soil has high infiltration while D soil has very low infiltration rate. Table 2-3 summarizes the group characteristics and Figure 2-5 shows the distribution of hydrologic soil groups. Generally, areas to the east contain a moderate to slow infiltration rate (hydrologic group C), while areas near the lakes on the western side of the watershed contain both slow (hydrologic group D) to moderately high infiltration rates (hydrologic group B).

HSG Runoff	Run off Potential	Infiltration Rate	Transmission Rate
А	Low	High	High
В	Moderate	Moderate	Moderate
С	High	Low	Low
D	High	Very Low	Very Low

Table 2-3: Relative Characteristics of Hydrologic Soil Groups

A commonly used soil attribute of interest is the K-factor, a coefficient used in the USLE. The K-factor is a dimensionless measure of a soil's natural susceptibility to erosion. Factor values may range from 0 for water surfaces to 1.00 (although in practice, maximum K-factor values do not generally exceed 0.67). Large K-factor values reflect greater potential for soil erodibility.

The compilation of K-factors from the SSURGO data was done in several steps. Soils are classified in the SSURGO database by map unit symbol. Each map unit symbol is made up of components and each component as part of that map unit is further broken down into horizons (or layers). The K-factor was determined by selecting the dominant components in the most surficial horizon per each map unit. The distribution of K-factor values in the DuPage River and Salt Creek watershed is shown in Figure 2-7. K-factors range from 0.15 to 0.43 in this watershed. Areas with the highest K-factor are dispersed throughout the watershed with the greatest concentration within DuPage County.

Figure 2-5: DuPage River/Salt Creek Watershed SSURGO Hydrologic Soil Group

Figure 2-6: DuPage River/Salt Creek Watershed SSURGO Drainage Class

2.5 Population

Circumstances in the DuPage River/ Salt Creek watershed today are not only the product of the geologic and natural processes that have occurred in the watershed, but also a reflection of human impacts and population growth. Development has changed the watershed's natural drainage system as channelization and dredging have replaced slow moving shallow streams and wetlands. This alteration has affected the way water runs off of the landscape both in increased volume and velocity, resulting in the potential increase in pollutant transport.

Census 2000 data in format of TIGER/Line Shape file were downloaded to analyze the population in the DuPage River/Salt Creek watershed. Census data were also available for groups of census blocks, but the original census block data was used since it is a finer resolution and, therefore, more accurate.

In 2000, approximately 4.8 million, people resided in the DuPage River/Salt Creek watershed, roughly 9,250 persons per square mile. The Salt Creek watershed accounts for nearly 80% of the population, but only 40% of the area. Census blocks with the greatest populations occur in the central and southern areas of the DuPage River watershed in Aurora, Naperville, and Joliet.

The Illinois Department of Commerce and Economic Opportunity provide population projections by municipality on their website ("Population Projections", 2005). Figure 2-8 depicts the projected percent population change in the watershed from 2000 to 2030. In general, the southern portion of the watershed is expected to have the most growth (~400%). The town of Plainfield, with a population of 13,038 persons in 2000, is projected to grow to 65,743 persons in 2030, an increase of approximately 404%. Also in the southern area of DuPage River watershed, Chinnahon, Minooka, and Shorewood are also expected grow in population by 400%, 287%, and 207%, respectively. Based on these data, development will grow dramatically in the southern portion of the watershed, but in general, the entire watershed will continue to increase in population over the years.

Figure 2-8: DuPage River/Salt Creek Watershed Population Projection

2.6 Climate

Northeast Illinois has a continental climate with highly variable weather. The temperatures of continental climates are not buffered by the influence of a large waterbody (like an ocean, inland sea or Great Lake). Areas with continental climates often experience wide temperature fluctuations throughout the year. Temperature and precipitation data were obtained from the Illinois State Climatologist Office website. The nearest monitoring station to the DuPage River/Salt Creek Watershed is the City of Wheaton, which is located in the central area of the watershed. For the DuPage River/Salt Creek watershed, the highest temperatures in the summer can range from high 80s to over 100 degrees Fahrenheit and the lowest winter temperatures might range between sub-zero and the teens. Precipitation in the form of rainfall is greatest in the growing season (April through September) (Figure 2-9).

Climate data were analyzed for the City of Wheaton between the years of 1950 and 2008, although data were not available for all years. The mean high summer temperature was 84.2° F and the mean low temperature in winter was 17.9° F. Mean annual high temperatures were approximately 61° F, while mean annual low temperatures were approximately 40° F (Table 2-4). Mean monthly precipitation data in Wheaton are displayed in Figure 2-9. Wheaton receives most of its precipitation in the spring and summer months, with maximum precipitation occurring in June (4.1 inches). The least amount of average rainfall precipitation occurs in February (1.6 inches). Annual total precipitation average was approximately 35.2 inches.

Impacts of the climate on the watershed can result from the warm summer temperatures and occasional long dry spells. These conditions lead to shallow water depth, warm water temperatures and low dissolved oxygen which makes the river inhospitable to less tolerant fish and invertebrate species. Additionally, heavy flooding can occur during the spring months, resulting in pollutant transport (SMC 2007; USFWS 1998).

	Average High (°F)	Average Low (°F)	Average Number of Days with High > 90 (°F)	Average Number of Days with Low < 32 (°F)	Mean (°F)

2.7 Hydrology

Understanding how water moves and flows is an important component of understanding a watershed. All of the parameters listed in the previous sections (i.e. topography, soils, and precipitation) impact hydrology. Hydrological data are available from the USGS website (<u>www.usgs.gov</u>, 2008). The USGS maintains stream gages throughout the U.S. and it monitors conditions such as gage height and stream flow, and at some locations, precipitation.

Four gage stations within the DuPage River/Salt Creek Watershed were chosen for stream flow data: East Branch of DuPage River at Downers Grove, IL (05540160), West Branch of DuPage River at Naperville, IL (05540130), DuPage River at Shorewood, IL (05540500), and Salt Creek at Western Springs, IL (05531500). The Salt Creek gage is located just upstream from the Addison Creek confluence near the confluence with the Des Plaines River. The East Branch is located upstream of the confluence with the West Branch. The West Branch of the DuPage River gage station is located immediately upstream of the confluence with the East Branch. Finally, the DuPage River at Shorewood is located immediately upstream of the confluence of the DuPage River mainstem and the Des Plains River. Figure 2-10 shows the location of these four USGS gages, and others, throughout the watershed.

Figure 2-11 depicts the stream flow measured at Salt Creek for the period of 1945 to 2007. The drainage area upstream of this gage was 115 square miles. The highest average monthly stream flows at Salt Creek were measured in April (233.0 cubic feet per second (cfs)), while the lowest monthly stream flows were measured in September (93.9 cfs). Overall the highest stream flow for this gage occurs during the late winter and spring months, while low flows occur during the fall. The annual stream flow for the Salt Creek gage was measured at about 136.8 cfs.

The East Branch DuPage gage drains an area of 26.6 square miles, and data at this gage exist from 1989 to 2007. Over this period the average stream flow of the East Branch was 49.5 cfs (Figure 2-12). Similar to the Salt Creek gage, stream flows were highest in the late winter and spring months with lower flows in the fall. Maximum average monthly flows occurred in April (69.0 cfs) while lowest average monthly flows occurred in September (35.2 cfs).

Figure 2-13 displays the stream flow measured at the West Branch DuPage River for the period ranging from 1988 to 2007. The drainage area upstream of this gage was 123 square miles and the highest average monthly stream flows at the West Brach were measured in April (230.6 cfs). Minimum average monthly stream flows of 102.0 cfs were measured in September. The annual stream flow for the West Branch gage was approximately 152.9 cfs.

Data from the main stem of the DuPage River gage exist from 1940 to 2007. This gage drains an area of 324 square miles and over the duration of its existence the average stream flow of the DuPage was 307.3 cfs (Figure 2-14). Peak stream flows occur in the late winter and spring months, with lower flows in the fall. Maximum monthly flow occurred in April (517.7 cfs) while lowest monthly flows were measured in September (189.9 cfs).

Churchill lagoon sometimes referred to as Churchill Woods Forest Preserve Lake was constructed in the 1930s by the Civilian Conservation Corps (CCC). It was created by damming the East Branch of the DuPage River. The surface area is 21 acres with a maximum depth of 8 feet and 3.67 miles of shoreline length. The 137 acre Churchill Woods Forest Preserve which contains the lagoon provides fishing, boating, and picnic and hiking facilities.

3.0 Public Participation and Involvement

The Illinois EPA is committed to keeping the watershed stakeholders and general public informed and involved throughout the TMDL process. Success for any TMDL implementation plan relies on a knowledgeable public to assist in follow-through required for attainment of water uses within their watershed. It is important to engage the local citizens as early in the process as possible by providing opportunities to learn and process information. This ensures that concerns and issues are identified at an early stage, so that they can be addressed and facilitate maximum cooperation in the implementation of the recommended courses of actions identified in the TMDL process. All stakeholders should have access to enough information to allay concerns, gain confidence in the TMDL process and understand the purpose and the regulatory authority or other responsible party that will implement recommendations.

Illinois EPA, along with AECOM, will hold up to two public meetings within the DuPage River/Salt Creek watershed throughout the course of TMDL development. This section will be regularly updated after public meetings have occurred. The Illinois EPA regularly meets with the DuPage River Salt Creek Workgroup to keep them informed on the TMDL progress.

General information regarding the process of TMDL development in Illinois can be found at <u>http://www.epa.state.il.us/water/tmdl</u>. This link also contains paths to notices of public meetings and other TMDL-related watershed information for the entire state of Illinois.

Background information regarding watersheds, watershed management, best management practices and the Clean Water Act (CWA) can be found on the EPA's water website at <u>http://www.epa.gov/watertrain/</u>.

For other reports and studies concerning the DuPage River and Salt Creek watershed, please visit the watershed workgroup website (<u>http://www.drscw.org/</u>). The website contains reports, data and additional links to other sources specifically related to this watershed.

4.0 Applicable Water Quality Standards and TMDL Targets

Water pollution control programs are designed to protect the beneficial uses of the water resources within the state. Each state has the responsibility to set water quality standards that protect these beneficial uses, also called "designated uses." Illinois waters are designated for various uses including aquatic life, primary contact (e.g., swimming, water skiing), secondary contact (e.g., boating, fishing), industrial use, drinking water, food-processing water supply and aesthetic quality. Illinois' WQS provide the basis for assessing whether the beneficial uses of the state's waters are being attained.

4.1 Illinois Pollution Control Program

The Illinois Pollution Control Board (IPCB) is responsible for setting WQS to protect designated uses. The federal Clean Water Act requires the states to review and update WQS every three years. Illinois EPA, in conjunction with USEPA, identifies and prioritizes those standards to be developed or revised during this three-year period. The IPCB has established four primary sets (or categories) of narrative and numeric water quality standards for surface waters: general use; public and food processing; secondary contact and indigenous aquatic life; and Lake Michigan basin standards. Each set of standards is intended to help protect various designated uses established for each category.

Illinois EPA is also responsible for developing scientifically based water quality criteria and proposing them to the IPCB for adoption into state rules and regulations. These responsibilities were subsequently assumed by the Illinois Department of Energy and Natural Resources who, in July 1995, became part of the Illinois Department of Natural Resources. The Illinois WQS are established in the Illinois Administrative Rules Title 35, Environmental Protection; Subtitle C, Water Pollution; Chapter I, Pollution Control Board; Part 302, Water Quality Standards.

Water resource management activities involving interstate waters are also coordinated with various interstate committees and commissions. The Illinois EPA participates in water-resource management activities of the Association of State and Interstate Water Pollution Control Administrators, International Joint Commission of the Great Lakes Water Quality Board, Ohio River Valley Water Sanitation Commission, Upper Mississippi River Conservation Committee, Upper Mississippi River Basin Association, Council of Great Lakes Governors, and other interstate committees and commissions.

4.2 Designated Uses

The waters of Illinois are classified by designated uses assessed in 2008 (Table 4-1). Designated uses applicable to the DuPage River/Salt Creek watershed include: aesthetic quality, aquatic life, and primary contact. The corresponding water quality standard classification for these designated uses is the General Use Standard.

Illinois EPA Designated Uses	Illinois Waters where Designated Use and Standards Apply	Applicable Illinois Water Quality Standards
Aquatic Life	Streams, Inland Lakes	General Use Standards
	Lake Michigan Basin waters	Lake Michigan Basin Standards
Aesthetic Quality	Inland Lakes	General Use Standards
	Lake Michigan Basin Waters	Lake Michigan Basin Standards
Indigenous Aquatic Life	Specific Chicago area Waters	Secondary Contact and Indigenous Aquatic Life Standards
Primary Contact	Streams, Inland Lakes	General Use Standards
	Lake Michigan Basin Waters	Lake Michigan Basin Standards
Secondary Contact	Streams, Inland Lakes	General Use Standards
	Lake Michigan Basin Waters	Lake Michigan Basin Standards
	Specific Chicago area Waters	Secondary Contact and Indigenous Aquatic Life Standards
Public and Food Processing Water Supply	Processing Water Waters	
Fish Consumption	Streams, Inland Lakes	General Use Standards
	Lake Michigan Basin Waters	Lake Michigan Basin Standards
	Specific Chicago Area Waters	Secondary Contact and Indigenous Aquatic Life Standards

Table 4-1: Illinois Designated Uses and Applicable Water Quality Standards

The General Use classification is defined by IPCB as: The General Use standards will protect the state's water for aquatic life, wildlife, agricultural use, secondary contact use and most industrial uses and ensure the aesthetic quality of the state's aquatic environment. Primary contact uses are protected for all General Use waters whose physical configuration permits such use.

4.3 Applicable Illinois Water Quality Standards

For aquatic life use assessments, Illinois EPA relies on biological indicators to provide direct reliable measures of aquatic community health and facilitates detection of cumulative impacts on aquatic life from multiple stressors. The primary biological measures used are the fish Index of Biotic Integrity, the macroinvertebrate Index of Biotic Integrity and the Macroinvertebrate Biotic Index. By relying more on biological indicators than on less reliable surrogates (e.g., water chemistry), the assessments of aquatic life

use achieve their primary purpose: to determine the degree to which a water body provides for the protection and propagation of fish, shellfish, and wildlife (i.e., the Clean Water Act's interim aquatic life goal). In these terms, an Illinois EPA assessment conclusion of Full Support for aquatic life use indicates conditions that meet the Clean Water Act's interim aquatic life goal. In a minority of streams, where biological data is not available, aquatic life use assessments are based primarily on physiochemical water data. The streams in this watershed were assessed at less than Full Support and water chemistry was analyzed for violations. Tables 4-2 and 4-3 summarize the potential impairments and standards that apply to streams and lakes within the DuPage River/Salt Creek Watershed.

Table 4-2: Summary of Water Quality Standards for Potential Impairments of Stream Segments in
the DuPage River/Salt Creek Watershed

Parameter	Units	General Use Water Quality Standard
Chloride	mg/L	500
Dissolved Oxygen	mg/L	For most waters ¹ : March-July > 5.0 min. $\&$ > 6.0- 7-day mean ¹ Aug-Feb > 3.5 min, > 4.0- 7-day mean ¹ , $\&$ > 5.5- 30-day mean ¹ . For waters with enhanced protection ¹ : March-July > 5.0 min $\&$ > 6.25- 7-day mean ¹ Aug-Feb > 4.0 min, > 4.5- 7-day mean ¹ , $\&$ > 6.0- 30-day mean ¹ .
Fecal Coliform	count/100 mL	May – October 200 ² , 400 ³
Manganese - Total	mg/L	1.0
рН	s.u.	Within the range of 6.5 – 9.0 except for natural causes
Phosphorus – Total ⁴	mg/L	0.05
Silver – Total	µg/L	5.0

1. Applies to the dissolved oxygen concentration in the main body of all streams, in the water above the thermocline of thermally stratified lakes and reservoirs, and in the entire water column of unstratified lakes and reservoirs. Additional dissolved oxygen criteria are found in 35 III Adm. Code 302.206, including the list of waters with enhanced dissolved oxygen protection and methods for assessing attainment of dissolved oxygen minimum and mean values.

2. Geometric mean based on a minimum of 5 samples taken over not more than a 30 day period.

3. Standard shall not be exceeded by more than 10% of the samples collected during any 30 day period.

4. Standard applies in particular inland lakes and reservoirs (greater than 20 acres) and in any stream at the point where it enters any such lake or reservoir.

Due to limited state resources, fecal coliform bacteria is not normally sampled at a frequency necessary to apply the General Use standard, i.e., at least five times per month during May through October, and very little data available from others are collected at the required frequency. Therefore, assessment guidelines are based on application of the standard when sufficient data is available to determine standard exceedances; but, in most cases, attainment of the *primary contact* use is based on a broader methodology intended to assess the likelihood that the General Use standard is being attained. To assess the *primary contact* use, Illinois EPA uses all fecal coliform bacteria from water samples collected in May through October, over the most recent five-year period (i.e., 2002 through 2006). Based on these water samples, geometric means and individual measurements of fecal coliform bacteria are compared to the concentration thresholds in Table C-16. To apply the guidelines, the geometric mean of fecal coliform bacteria concentration is calculated from the entire set of May through October water samples, across the five years. No more than 10% of all the samples may exceed 400/100 ml for a water body to be considered Fully Supporting.

As for the application of the dissolved oxygen standard, DuPage River segments GB-11 and GB-16 are waters with enhanced protection according to 35 III Adm. Code 302.206, Figure 4-1. Waters with enhanced protection have a more stringent standard than all other waters of the State. These waters were chosen based on the potential biota and the dissolved oxygen needed for said biota to thrive. All other waters in the DuPage River and Salt Creek watersheds are not considered enhanced protection waters and the standard for "most waters" applies. DuPage River GB-16 is impaired for dissolved oxygen on the 2008 303(d) List according to the enhanced protection dissolved oxygen standard.

e C-16. Guidelines s.	for Assessing <u>Primary Contact</u> Use in Illinois Streams and
Degree of Use Support	
Fully Supporting (Good)	No exceedances of the fecal coliform bacteria standard in the last five years <u>and</u> the geometric mean of all fecal coliform bacteria observations $\leq 200/100$ ml, <u>and</u> $\leq 10\%$ of all observations exceed 400/100 ml.
	One exceedance of the fecal coliform bacteria standard in the last five years (when sufficient data is available to assess the standard)
Not Supporting (Fair)	or The geometric mean of all fecal coliform bacteria observations in the last five years 200/100 ml, and >10% of all observations in the last five years exceed 400/100 ml or The geometric mean of all fecal coliform bacteria
	observations in the last five years $>200/100$ ml, and $\le 25\%$ of all observations in the last five years exceed 400/100 ml.
Not	More than one exceedance of the fecal coliform bacteria standard in the last five years (when sufficient data is available to assess the standard)
Supporting (Poor)	or The geometric mean of all fecal coliform bacteria observations in the last five years >200/100 ml, <u>and</u> >25% of all observations in the last five years exceed 400/100 ml

Figure 4-1: Segments with Enhanced Protection in the DuPage River/Salt Creek Watershed

4.4 TMDL Targets

In order for a waterbody to be listed as Fully Supporting, it must meet all of its applicable designated uses. Because WQS are designed to protect those designated uses, a pollutant's numeric WQS is therefore used as the target or endpoint for establishing a TMDL. Table 4-3 summarizes the endpoints that will be used in the TMDL development for the DuPage River/Salt Creek watershed.

Segment ID	Waterbody Name	Impairment	TMDL Target	Units
IL_GL	Salt Creek	Fecal Coliform	<400	cfu/100 ml

Table 4-3: TMDL Targets for Impaired Waterbodies in the DuPage River/Salt Creek Watershed

Segment ID	Waterbody Name	Impairment	TMDL Target	Units
IL_RGG	Churchill Lagoon	Total Phosphorus	<0.05	mg/L

Segment GB-16 is considered a water with enhanced protection for dissolved oxygen and the enhanced protection dissolved oxygen standard applies
 * Refer to Table 4-2 for the dissolved oxygen standard

5.0 Water Quality Assessment

This section discusses the pollutants of concern for the DuPage River/Salt Creek watershed. The available water quality data were analyzed, assessed, and compared with WQS to verify the impairments of the 16 stream segments and Churchill Lagoon. The water quality conditions in the watershed were evaluated by sampling location and time. Available point and non-point source data were also assessed and discussed in more detail throughout the remainder of the section.

5.1 Water Quality Data

The DuPage River/Salt Creek Watershed has 17 impaired waters within its drainage area. Figure 5-1 shows the water quality data stations within the watershed that contain data relevant to the impaired segments. The following sections address both stream and lake impairments.

Data analysis was focused on all available data collected since the year 2000. The information presented in this section is a combination of both legacy and modernized USEPA Storage and Retrieval (STORET) database and data from the Illinois EPA database, Sierra Club, Wheaton Sanitary District, Metropolitan Water Reclamation District of Greater Chicago, and DuPage River Salt Creek Workgroup. Table 5-1 contains the monitoring entities for each water segment.

Data relevant to impairments were compiled for each impaired waterbody and summarized. The following parameters were grouped by impairment and discussed in relation to the relevant Illinois numeric WQS. For all assessments, compliance was determined at the surface of a stream or at the one-foot depth from the lake surface.

Segment	Parameter	Entity
GB-01	Silver	Illinois EPA
GB-11	Chloride	Illinois EPA
	Fecal	Illinois EPA
GB-16	DO	Illinois EPA
	Fecal	Illinois EPA
	DO	DRSCW, Illinois EPA, Sierra Club

Figure 5-1: Monitoring Stations Used for Assessing Impairments

5.1.1 Fecal Coliform

Figures 5-2 through 5-4 contain the available fecal coliform data. Data is available from the years indicated in the time series graphs, but for statistical purposes more recent data was used shown in Table 5-2, ranging from 1999 to 2007. The WQS for fecal coliform is a 200 cfu/100ml geometric mean based on a minimum of five samples taken over any 30 day period or a 400 cfu/100ml maximum not to be exceeded in more than 10% of samples taken during any 30 day period. Due to the unlikelihood of having five fecal coliform samples per month upon which to judge compliance, a single exceedance of 400 cfu/100 ml is often interpreted as an instantaneous maximum for assessment purposes.

Segment	Stations	Data Years	No. of Samples	Violations >200	Violations >400	Min	Мах	Average	Median

Figure 5-4. Fecal Coliform Time Series for GL, GL-09, GL-10, GL-19 and GLA-02

5.1.2 Dissolved Oxygen

The DO WQS for all segments except GB-16 is a 5.0 mg/L instantaneous minimum for March through July and 3.5 mg/L for August through February. Segment GB-16 is subject to enhanced protection so the WQS is a 5.0 mg/L instantaneous minumum for March through July and 4.0 mg/L for August through February. Five waterbody segments were determined to be impaired for low DO based on this criterion. Data ranged from 1964 to 2007. A data summary for recent dissolved oxygen data is contained in Table 5-3. Figure 5-5 contains summary information for Illinois EPA monthly DO data for GB-16 enhanced waterbody. Figures 5-6 and 5-7 contain continuous hourly monitoring data for GB-16 and GBK-05. Figure 5-8 contains monthly data for GBK-05, GBK-14, GBKA and GBK-09. Figure 5-9 contains continuous hourly data for GBK-09.

Segment	Stations	Data Years	Observations	Violations	Minimum
GB-16	IEPA GB-08 IEPA GB-16*	2000- 2006	443	28	3.54

Figure 5-9. Dissolved Oxygen Data for GBK-09 Provided by DuPage River Salt Creek Workgroup (Continuous Monitoring)

5.1.3 pH

The WQS dictates an acceptable pH range between 6.5 and 9.0 s.u. Six segments are slated for TMDL development and all indicated at least one violation within the available data. Figure 5-10 displays pH data available since 1999 and Table 5-4 contains corresponding summary information.

Table	5-4:	Recent	pН	Data	Summary
-------	------	--------	----	------	---------

Figure 5-10: pH Distribution 1999 to 2007

5.1.4 Manganese

The applicable WQS for manganese is 1 mg/L. Table 5-5 and Figure 5-11 summarize available manganese data for a segment on the West Branch of the DuPage River (IL_GBK-14), the only waterbody impaired for manganese. Available total manganese data ranged mostly from 2001 to 2007 with a few data points in 1983 and 1984.

Table 5-5: Manganese Data Summary

Segme	nt	Units	# Observations	# Violations	Min	Max	Average	Median	Standard Deviation
IL_GBK	14	mg/L	45	1	0.02	1.23	0.15	0.11	0.17

Figure 5-11: Manganese Time Series for IL_GBK-14

5.1.5 Chloride

Two chloride exceedances were recorded at the IL_GB-11 segment of the DuPage River. The general use water quality standard for chloride is 500 mg/L and available data used for assessment ranged from 1968 to 2005. Table 5-6 and Figure 5-12 summarize the available chloride data.

Segment	Units	# Observations	# Violations	Min	Max	Average	Median	Standard Deviation
IL_GB-11	mg/L	287	2	24	1060	182.9	174	90.4

Figure 5-12: Chloride Time Series for IL_GB-11

5.1.6 Silver

Two segments were listed for silver impairment within the DuPage River/Salt Creek Watershed, IL_GB-01 on the main stem and IL_GBK-09 on the West Branch of the DuPage River. Table 5-7 and Figure 5-13 summarize total silver data. Ambient data indicate that the silver water quality standard of 5 μ g/L was violated on 5 occasions, one in 2000 on IL_GB-01 and the other 4 on IL_GBK-09. Data used for analysis ranged from 1980 to 2003.

Segment	Units	# Observations	# Violations	Min	Max	Average	Median	Standard Deviation
IL_GB-01	µg/L	18	1	0	16	3.44	3	3.29
IL_GBK-09	µg/L	195	4	0	9	3.21	3	0.90

Figure 5-13: Silver Time Series for IL_GB-01 and IL_GBK-09

5.1.7 Total Phosphorus

The numeric water quality criteria for total phosphorus is a maximum concentration of 0.05 mg/L and is applicable only to lakes with a surface area of 20 acres or greater. Phosphorus concentrations for Churchill Lagoon (IL_RGG) are summarized in Table 5-8 and Figure 5-14. Data used for assessments were only available in 2001.

Table 5-8: Phosphorus	s Data Summary
-----------------------	----------------

Segment	Units	# Observations	# Violations	Min	Max	Average	Median	Standard Deviation
IL_RGG	mg/L	6	6	0.976	1.540	1.294	1.310	0.210

Figure 5-14. Phosphorus Data for RGG

5.2 Point Sources

A number of point source dischargers actively maintain National Pollutant Discharge Elimination System (NPDES) permits within the DuPage River/Salt Creek watershed. Discharge Monitoring Reports (DMRs) for each discharger will be required for the Stage 3 analysis of the TMDL, as available data will be quantified and analyzed to determine the point source loading for each receiving water. Table 5-9 lists the existing NPDES permits as provided by EPA's Enforcement Compliance History Online (ECHO) database. Geographic locations are provided in Figure 5-8.

Phase I of the NPDES Storm Water program began in 1990 and required medium and large municipal separate storm sewer systems (MS4s) to obtain NPDES coverage. The expanded Phase II program began March 2003 and requires small MS4s in urbanized areas to obtain NPDES permits and implement six (6) minimum control measures. An urbanized area as delineated by the Bureau of Census is defined as a central place or places and the adjacent densely settled surrounding area that together have a residential population of at least 50,000 people and an overall population density of at least 500 people per square miles. Table 5-10 lists the MS4s within the DuPage River/Salt Creek Watershed and Figure 5-17 indicates the location.

MS4 Permit Requirements:

- 1. Develop a storm water management program comprised of best management practices (BMPs) and measurable goals for each of the following six minimum control measures:
 - o Public education and outreach on storm water impacts
 - o Public involvement and participation
 - o Illicit discharge detection and elimination
 - o Construction site storm water runoff control
 - o Post construction storm water management in new development and redevelopment
 - o Pollution prevention/good housekeeping for municipal operations
- 2. Submit a completed Notice of Intent. Operators can choose to share responsibilities for meeting the Phase II program requirements. Those entities choosing to do so may submit jointly with other municipalities or governmental entities. The Notice of Intent form is available below.
- 3. Submit an annual report to IEPA in June of each year starting in 2004. The reports must include:
 - The status of compliance with the permit conditions, including an assessment of the BMPs and progress toward the measurable goals;
 - o Results of any information collected and analyzed, including monitoring data;
 - o A summary of the storm water activities planned for the next reporting cycle;
 - o A change in any identified best management practices or measurable goals;
 - If applicable, notice of relying on another governmental entity to satisfy some of the permit obligations.

Figure 5-16: Municipal Separate Storm Sewer Systems in the DuPage River/Salt Creek Watershed

5.3 Non-Point Sources

The DuPage River/Salt Creek watershed is dominated by urban growth; current land use is approximately 65% urban. Further, over 20% of the remaining land use is considered agricultural, a primary source of non-point source pollution in waterbodies. To properly manage and maintain water quality in the DuPage River/Salt Creek watershed, the impacts associated with new development and agriculture must be carefully evaluated.

Urban and suburban development can adversely impact water quality in a number of ways. During the construction phase of development, soils destabilized as a result of clearing, grading, and excavation are subject to increased erosion by wind and water. These eroded soils can be carried offsite and deposited in receiving waters such as lakes, rivers and wetlands. Adverse impacts associated with such sediment loading include increased turbidity and habitat modification, including smothering of invertebrates and covering spawning beds. Typically, the construction phase is relatively short-lived; however, the impacts to receiving waters from poorly managed construction activities may be extremely severe and the effects can endure long after the project is over.

Post-construction receiving water quality impacts may become more pronounced due to potentially dramatic changes to the area's hydrology (reduced baseflow and exaggerated peak flow volumes), and the change in land use compared to predevelopment conditions. The increase in impervious areas, such as roadways and parking lots, can often result in increased runoff rates and volumes. This can result in increased streambank erosion which can lead to increased sediment loading and its associated water quality problems. The increased runoff can also accelerate the transport of land-borne pollutants such as heavy metals, oil and grease, pesticides, fertilizers and other nutrients, and toxic organic contaminants. Increased imperviousness can also cause significant elevations in receiving water temperatures during summer months. Winter road deicing activities can contribute high levels of chlorides or sediment.

Agricultural practices in the DuPage River/Salt Creek watershed can also adversely impact water quality. The dominant crops found in the watershed are soybean (43%) and corn (38%), but other harvested crops include winter wheat, grain, and hay. Fertilizers used for such crops typically consist of nitrogen and phosphorus and are considered a potential source of nutrient enrichment in waterbodies.

Water quality impacts may be evaluated in terms of short-term impacts, and long-term impacts. Individual runoff events can cause short-term impacts to receiving waters, and are typically on a timescale of hours to days. Changes to the dry and wet weather hydrology, streambank morphology, and water chemistry of the receiving water are considered long-term impacts. Such long-term chemical impacts are most critical for those waters with longer residence times such as lakes and wetlands, and slow-moving stream segments. With regards to urban development and agriculture, pollutant concentrations are best used to evaluate short-term effects, while pollutant loadings are appropriate for assessing long-term impacts. DuPage River/Salt Creek watershed planners and developers need to understand these impacts and carefully plan in order to mitigate the negative water quality impacts of development and agriculture.

5.4 Watershed Studies and Other Watershed Information

There are a number of groups in the watershed that have collected and developed information and studies that are pertinent to this TMDL. Listed below is some of the information found for this watershed.

Chloride Usage Education and Reduction Program Study

This study was developed by the DuPage River Salt Creek Workgroup (DRSCW) in response to the Chloride TMDL previously approved. The TMDL identified road salt as a major cause of the chloride impairment. The Study evaluated the current road salting practices and recommends alternatives to reduce chloride. The report is available at the DRSCW websitehttp://www.drscw.org/reports/ChlorideRecomendations.Final Report.pdf

• Stream Dissolved Oxygen Improvement Feasibility Study for Salt Creek and East Branch DuPage River-

This study was developed by the DRSCW in response to the dissolved oxygen TMDL previously approved. The goal of the Study was to determine the feasibility and benefits of the removal or modification of dams, and of the construction and operation of in-stream aeration projects on improved dissolved oxygen in Salt Creek and the East Branch of the DuPage River. The first part of this study which characterized the existing conditions is available at this websitehttp://www.drscw.org/dostudy.htm. The final draft dissolved oxygen feasibility study was completed in June 2009.

• Bioassessment of West and East Branch DuPage and Salt Creek Watersheds-

This study was developed by the DRSCW. Its objectives are to determine the extent to which biological assemblages are impaired and determine the stressors and sources that are associated with those impairments. The first stage of the study was the bioassessment plan which identifies the monitoring procedure and requirements for a watershed based biological assessment of the watersheds. This report is available at the DRSCW websitehttp://www.drscw.org/reports/bioassessplan.pdf. The final report that includes results of the monitoring is scheduled to be finalized in January 2009.

• Illinois EPA 319 Funding-

Illinois EPA has provided Nonpoint Source Pollution Control Program 319 funding for the DRCSW. Funds were used towards a local project coordinator, the expansion of the dissolved oxygen monitoring and completions of both the bioassessment and dissolved oxygen feasibility studies.

Assessment of Impacts of Dams on the DuPage River-

This Study was done by the Conservation Foundation and the purpose was to assess the impact of man-made dams on fish passage, recreational uses and water quality. It includes and physical assessment of the dams and characterizes biological data. It indicates that dams on the DuPage River are a significant contributor to the overall degradation of native aquatic species and their habitat. It also indicates the dams might not have a significant effect on water quality, but create a safety hazard for all recreational use. This report is available at the Conservation Foundation website-http://www.theconservationfoundation.org/images/stories/pdf/wp/assessment_of_dupage_river_dams.pdf.

6.0 TMDL Approach and Data Needs

This chapter discusses the methodology that may be used for the development of TMDLs for the DuPage River/Salt Creek watershed. While a detailed watershed modeling approach can be advantageous, a simpler approach is often able to efficiently meet the requirements of a TMDL and yet still support a TMDL-guided and site-specific implementation plan. The final selection of a methodology will be determined with consultation with the Illinois EPA based on following factors:

- Fundamental requirements of a defensible and approvable TMDL
- Data availability
- Fund availability
- Public acceptance
- Complexity of waterbody

A simpler approach shall be used as long as it adequately supports the development of a defensible TMDL. If it is deemed that this approach will not suffice, a more sophisticated modeling approach will be recommended for analysis to help better establish a scientific link between the pollutant sources and the water quality indicators for the attainment of designated uses. Methodology for estimating daily loads will depend on available data as well as the selected analysis.

6.1 Recommended Modeling Approach for Fecal Coliform

Many states currently use load duration curves for fecal coliform TMDLs for its simplicity and effectiveness. Load duration curves use water quality criteria, ambient concentrations, and observed flows to estimate loading capacities for streams under various flow conditions.

The first step in this process is to obtain an appropriate stream flow record. For this TMDL, USGS gages are found throughout the watershed.

Flow duration curves are developed from streamflow records spanning multiple decades. The flow duration curve is based on flow frequency which provides a probability of meeting or exceeding of a given flow. The duration curve is broken into hydrologic categories where high flows represent a duration interval of 0-10%, moist conditions represent 10-40%, mid-range flows 40-60%, dry conditions 60-90% and low flows 90-100%.

Once the flow duration curve is established, a load duration curve can be generated by multiplying streamflow with the numerical water quality standard and a conversion factor to obtain the load per day for a given streamflow. Individual measurements can be plotted against the load duration curve to evaluate patterns of impairment. Values that fall above the load duration line indicate an exceedance of the daily load and hence, water quality standard. These data can aid in determining whether impairment occurs more frequently in one of the hydrologic categories (wet, moist, mid-range, dry or low).

The margin of safety (MOS) for duration curves can be implicit or explicit. Implicit MOS are derived from the inherent assumptions in establishing the water quality target (conservative assumptions). Explicit MOS include setting the water quality target lower than the WQS or not allocating a portion of the allowable load. For the DuPage River/Salt Creek TMDL, an implicit margin of safety is proposed. The load duration analysis performed for this TMDL will be conservative because the TMDL target (no more than 200 cfu/100 ml at any point in time) is more conservative than the more restrictive portion of the fecal coliform water quality standard (geometric mean of 200 cfu/100 ml for all samples collected May through October).

Wasteload allocations (WLA) will be based on NPDES permit limits. Average discharge flow and permit limits will be used to calculate a daily load and serve as the WLA. WLAs for NPDES-permitted stormwater discharges, including current and future Municipal Separate Storm Sewer Systems (MS4s), "Urbanized" areas, construction and industrial discharges and sanitary sewer overflows (SSOs) that do not have numerical effluent limitations will be expressed as a percent reduction instead of a numerical target. The load allocation (LA) for all non-regulated sources, including non-point sources, will also be expressed as a percent reduction. The percent reduction is based on the maximum reduction required to meet WQS plus a margin of safety under critical conditions.

The load reduction for fecal coliform can be established for each flow regime based on load duration curve analysis. Alternatively, a critical condition (worst scenario) can be established by comparing all flow regimes. It is defined as the greatest reduction needed to meet WQS among all hydrologic categories. For example, if an 89% reduction is required to meet the TMDL under wet conditions and a 50% reduction is required under dry conditions, an 89% reduction could be required under all hydrologic conditions to ensure that the TMDL is protective under in all hydrologic conditions. The appropriate method will be selected during Stage 3.

Seasonality of loading will also be evaluated. Flow duration intervals will be plotted by month to determine if there is a strong seasonal component. Although this will not change allocations, this may assist in implementation planning.

6.2 Recommended Modeling Approach for Dissolved Oxygen

QUAL-2K, a spreadsheet model that is based on the fundamental Streeter-Phelps DO sag equation, is recommended for DO TMDL development for impaired waterbodies in the DuPage River/Salt Creek watershed. QUAL-2K is a one-dimensional, steady-state model that can accommodate point and non-point source loading and is capable of modeling DO in streams and well-mixed lakes. QUAL-2K is an updated version of QUAL-2E and has been developed using a Microsoft Excel interface. QUAL-2K allows for model segmentation, the use of two forms of carbonaceous BOD (both slow and rapid oxidizing forms), and is also capable of accommodating anoxia and sediment – water interactions. While the model is simplistic in nature, it is capable of estimating critical BOD concentrations associated with in-stream DO concentrations of 5 mg/L.

6.3 Recommended Modeling Approach for Total Phosphorus

In the event that dam removal is not performed at Churchill Lagoon and the waterbody continues to be subject to WQS, ongoing sampling will provide data to be used for TMDL development. An export coefficient model linked to empirical in-lake response models will be used to determine existing loading and load reductions required to bring Churchill Lagoon into compliance with current WQS. This model, ENSR-LRM (lake response model), was developed by ENSR and has been used on more than 35 lake TMDLs.

ENSR-LRM uses export coefficients for runoff, groundwater and nutrients to estimate loading as a function of land use. Yields will be assigned to each defined parcel (sub-watershed) in the lake watershed. Loading estimates will be adjusted based on proximity to the lake, soils and major Best Management Practices (BMPs) in place. Model yields will be compared to measured data, where available. Export coefficients and attenuation factors will be adjusted such that model loading accurately reflects actual loading based on sample data and measured in-lake concentrations.

Watershed and subwatershed boundaries will be delineated based topography. Watershed land use will be determined using publically available GIS data layers from the Illinois Natural Resource Geospatial Data Clearinghouse, or similar source. ENSR-LRM will be set-up on a sub-watershed level using available land use and average annual precipitation. The spreadsheet-based export coefficient model allows the user to select watershed yield coefficients and attenuation factors from a range appropriate in the region. The model also includes direct inputs for atmospheric deposition, septic systems, point sources, waterfowl and internal loading from lake sediments.

The generated load to the lake is processed through five empirical models: Kirchner & Dillon 1975, Vollenweider 1975, Larsen & Mercier 1976, Jones & Bachmann 1976 and Reckhow 1977. These empirical models predict in-lake phosphorus concentrations based on loading and lake characteristics such as mean water depth, volume, inflow, flushing and settling rates. Predicted in-lake phosphorus is compared to measured data. An acceptable agreement between measured and predicted concentrations indicates loading estimates are appropriate for use in the preparation of a TMDL. Adjustments to the loading portion of the model are made when necessary based on best professional judgment to ensure acceptable agreement between measured and predict chlorophyll concentrations and water clarity (Secchi disk transparency). ENSR-LRM also includes a statistical evaluation of algal bloom probability.

Once the model has been calibrated to existing conditions, adjustments to the model can be made to determine predevelopment conditions and the load reductions necessary to meet WQS. In some instances, waterbodies are naturally eutrophic and may not achieve numerical WQS even under predevelopment conditions. In such instances, site specific criteria or maximum practical reductions have been used for TMDL targets and are proposed.

ENSR-LRM is most effective when calibrated with water quality data for the target system, but can be used with limited data. While it is a spreadsheet model with inherent limitations on applied algorithms and resultant reliability of predictions, it provides a rational means to link actual water quality data and empirical models in an approach that addresses the whole watershed and lake. ENSR-LRM is an easy and efficient method of estimating current loads to lakes as well as providing predictions on lake response under countless loading scenarios.

ENSR-LRM, as well as most simplified lake models, predicts phosphorus concentrations and estimates loading on an average annual basis. As required by the EPA, the TMDL must be expressed on a daily basis. However, there is some flexibility in how the daily loads may be expressed (US EPA, 2006). Several of these options are presented in "Options for Expressing Daily Loads in TMDLs" (US EPA, 2007). For TMDLs based on watershed load and in-lake response models providing predictions on an annual basis, the EPA offers a method for calculating the maximum daily limit based on long-term average and variability. This statistical approach is preferred since long periods of continuous simulation data and extensive flow and loading data are not available. The following expression assumes that loading data are log-normal distributed and is based on a long term average load calculated by the empirical model and an estimation of the variability in loading.

MDL= LTA *
$$e^{[z\sigma - 0.5\sigma^{2}]}$$

Where: MDL = maximum daily limit LTA = long-term average Z = z-statistic of the probability of occurrence $\sigma^2 = \ln(CV^2 + 1)$ CV= coefficient of variation

Data from similar lakes will be used in situations where there are not enough data to determine probability of occurrence or coefficient of variation for the impaired waterbody.

MOS for phosphorus using this method is implicit. There is substantial uncertainty in concentration inputs to the models related to the timing of sampling and analytical methods, and the empirical equations used to predict in-lake phosphorus concentrations, mean and maximum chlorophyll, Secchi disk transparency, and bloom probability also introduce variability into the predictions.

WLA will be determined based on NPDES permit effluent limitations and average flow. WLAs for NPDESpermitted stormwater discharges, "Urbanized" areas, construction and industrial discharges that do not have numerical effluent limitations will be expressed as a percent reduction instead of a numerical target. WLA for MS4s will be based on their urbanized boundaries and at high flow regimes when stormwater events are expected. WLA for SSOs will be zero since these are illicit discharges and not allowed. The SSO issues should be addressed by MS4 program.

The reduction percentage for nonpoint source will be established based on LAs and existing load under critical condition. Critical conditions for lakes typically occur during the summertime, when the potential (both occurrence and frequency) for nuisance algal blooms are greatest. The loading capacity for total phosphorus is set to achieve desired water quality standards during this critical time period and also provide adequate protection for designated uses throughout the year. The target goal is based on average annual values, which is typically higher than summer time values. Therefore a LA based on average concentrations will be sufficiently low to protect designated uses in the critical summer period.

The ENSR-LRM derived TMDL takes into account seasonal variations because the allowable annual load is developed to be protective of the most sensitive (i.e., biologically responsive) time of year (summer), when conditions most favor the growth of algae. Maximum annual loads are calculated based on an overall annual average concentration. Summer epilimnetic concentrations are typically lower than the average annual concentration, so it is assumed that loads calculated in this manner will be protective of designated uses in the summer season, when most critical. It is possible that concentrations of phosphorus will be higher than the annual average during other seasons, most notably in the spring, but higher phosphorus levels at that time does not compromise uses. The proposed TMDL is expected to protect all designated uses of the impaired waterbody.

6.4 Recommended Modeling Approach for pH

QUAL-2K is also capable of estimating in-stream pH. In the modeling framework, both total inorganic carbon and alkalinity are simulated based on inputs. Using these two quantities, the model then simulates in-stream pH. These calculated values will then be the basis for recommending TMDL reductions if necessary.

6.5 Recommended Modeling Approach for Metals

Similar to fecal coliform, load duration curves are recommended for the chloride, silver, and manganese TMDLs. The duration curve will be used to estimate the percent of time that a water quality standard is exceeded. The wasteload allocations will be based on criteria concentrations which will then be converted into a distribution of allowable loads as a function of daily flow.

6.6 Data Needs

Effective TMDL development heavily relies on site-specific data. Sufficient flow and water quality data are required for the evaluation of water conditions and for model calibration. In fact, data availability often dictates the modeling approach used for various watersheds. Five types of data are crucial for the DuPage River/Salt Creek Watershed TMDL development:

- Flow data
- Meteorological data
- Water quality data
- Watershed and waterbody physical parameters
- Source characteristics data

Most necessary data are available for the TMDL with the exception of some water quality data. Available phosphorus data were limited to one year for Churchill Lagoon. Ongoing sampling will help to address the Churchill Lagoon data gaps.

Point source discharge data from all NPDES permittees within the watershed will also be necessary for the Stage 3 analysis. Individual NPDES permits, DMRs, and measured discharge data are all pertinent to TMDL development. Data will be obtained either using EPA's ECHO database or by directly contacting permittees.

Stage 1 Responsiveness Summary

This page left blank for double-sided printing

Appendix E: Stage One Responsiveness Summary

This responsiveness summary responds to substantive questions and comments received during the public comment period from January 16, 2009 through April 17, 2009 postmarked, including those from the January 28, 2009 public meeting discussed below.

What is a TMDL?

A Total Maximum Daily Load (TMDL) is the sum of the allowable amount of a pollutant that a water body can receive from all contributing sources and still meet water quality standards or designated uses. This TMDL is for the DuPage River/Salt Creek watersheds. In Illinois, developing a TMDL is a three stage process and this is a stage one report which contains the watershed characteristics, impairments and potential sources. After the stage one report, stage two and stage three will proceed. Stage two would include additional monitoring and stage three is the required modeling, allocations and reductions for each TMDL impairment and would also include an implementation plan.

Background

The DuPage River and Salt Creek watersheds drain approximately 332,600 acres and lies mainly in Cook, DuPage and Will counties. Land use in the DuPage River watershed is 65% urban, 21% agriculture and 10% forest while in Salt Creek it is 85% urban and 12% forest. Waters impaired in this watershed are DuPage River, East Branch DuPage, West Branch DuPage, Spring Brook, Salt Creek, Addison Creek and Churchill Lagoon. The DuPage River is listed on the Illinois EPA 2008 Section 303(d) List as being impaired for chloride, fecal coliform, dissolved oxygen and silver. East Branch is impaired for fecal coliform and pH. West Branch is impaired for dissolved oxygen, fecal coliform, silver, manganese and pH. Spring Brook is impaired for dissolved oxygen and fecal coliform. Salt Creek is impaired for fecal coliform and pH. Churchill Lagoon is impaired for phosphorus. The Clean Water Act and USEPA regulations require that states develop TMDLs for waters on the Section 303(d) List. Illinois EPA develops TMDLs allocations for impairments with numeric water quality standards, but some non-numeric standards may be addressed through the implementation plan. Best Management Practices (BMPs) put in place for TMDL impairments may reduce other parameters associated with it.

Public Meetings

A stage one public meeting was held in Elmhurst on January 28, 2009. The Illinois EPA provided public notices for all meetings by placing an ad in the local newspapers in the watershed; the Chicago Daily Herald, The Will-South DuPage Report and the Central Cook Suburban. These notices gave the date, time, location, and purpose of the meetings. It also provided references to obtain additional information about this specific site, the TMDL Program and other related issues. Individuals and organizations were also sent the public notice by first class mail. An additional stakeholder meeting was held March 31, 2009 in Plainfield, IL. The draft TMDL Report was available for review at the Elmhurst City Hall and on the Agency's web page at http://www.epa.state.il.us/water/tmdl .

The first public meeting on January 28, 2009 started at 6:00 p.m. and was attended by approximately 50 people. The second stakeholder meeting on March 31, 2009, started at 10:00 am and was attended by 20 people. The meeting record remained open until midnight, April 17, 2009.

There will be a public meeting for the stage three TMDL report in the future and a responsiveness summary will be developed for this meeting also.

Questions and Comments

1. The stakeholders in the watershed were not given the opportunity to provide input on how the stage 1 report was to be conducted. Many of the same issues discovered in the first TMDLs are also appearing in this report. Why were we not given the opportunity to provide input in the early stages of planning and conducting the report?

Response

The Illinois EPA published the Illinois Integrated Water Quality Report and Section 303(d) List- 2006 in June of 2006. This document lists all the waters for TMDL development in the next two years. All of the segments for this TMDL were listed in Table C-29 of the Integrated Report. The Illinois EPA holds the first public meeting at the beginning of the TMDL process- in stage one. The basic watershed information is completed in this stage and presented to the public. This is also the stage we request any other relevant data in the watershed and public input. Illinois EPA also participates in the DuPage River Salt Creek Workgroup and keeps the Workgroup updated on TMDL issues.

2. The water quality standard for fecal coliform is "based on a minimum five samples taken over a 30 day period". However, Illinois EPA does not have the appropriate number of samples and therefore has elected to use an alternative water quality standard. Illinois EPA should obtain the necessary data to use the more preferred standard for assessment purposes.

Response

Illinois EPA does sample at the frequency required by one part of the standard. Stations that are assessed for primary contact in this watershed are sampled approximately monthly. If available, five years of data are used for the primary contact assessments. For this TMDL, most of the assessments were based on data that were received from outside sources. From those stations sampled by outside sources, Illinois EPA will accept sampling at the correct frequency when the standard is applied- May through October. If their data become available this year, they will be used for the TMDL. The DRSC Workgroup is developing a sampling plan for this watershed as part of the implementation process.

3. The report does not state how the effect of animals on fecal coliform will be addressed. Illinois EPA stated in the public meeting that they would try to use some data that have been gathered in other states but the data may not be comparable to this watershed and therefore assumptions may have to be made. This will greatly decrease the reliability of the modeling and ultimately the wasteload allocations and TMDL. Therefore, it is imperative that Illinois EPA obtain the appropriate data and perform the necessary studies to properly account for the effect of wildlife on fecal coliform.

Response

Illinois EPA will be addressing the bacteria impairments using the load duration curve analysis. Bacteria data and flow data are the basis of this analysis. Loads are ranked per flow and one can which flow periods in which there are exceedences of fecal coliform bacteria. By using this approach, sources can be tracked by the flow period. For example, if point sources are causing the majority of the problem, exceedences will be seen even in low flow periods when there is no precipitation causing runoff. If the main problem is runoff related, exceedences will be seen in high and medium flow periods only. The analysis also shows the exceedences that are due to storm flows. Exceedences due to wildlife would be expected in high to high-medium flows. Illinois EPA is not aware of any livestock facilities in this watershed and does not have adequate estimates of wildlife populations in this area. If anyone is aware of these data, Illinois EPA would like to obtain this information.

4. Through studies performed by DRSCW, it has been clearly shown that sediment oxygen demand (SOD) has a profound effect on the QUAL-2K model for DO. This model is very sensitive to SOD and therefore SOD monitoring data are critical when modeling for DO. Illinois EPA must obtain the required SOD data in order to properly perform water quality modeling for DO.

Response

In response to suggestions made at the Stage One Public Meeting, Illinois EPA will be obtaining SOD samples from the West Branch DuPage River.

5. Illinois EPA is going to use monthly monitoring reports from publicly owned treatment works (POTWs) to provide data for the QUAL-2K model when studying the DO parameter. However, Illinois EPA should use actual data that are readily available.

Response

Illinois EPA typically uses the designed average flow (DAF) for NPDES facilities discharging in the watershed. It was brought to our attention at the meeting that this may over-estimate loads from these sources and flow data obtained from the individual facilities would best represent loads in the model. NPDES facilities are not required to give Illinois EPA this flow information, but Illinois EPA will work with facilities to obtain it.

6. The Report does not state how it will address wet weather flow. Illinois EPA should obtain the necessary wet weather data to determine how they are going to address wet weather flows.

Response

See response to question 4 for information on how the load duration curves determine wet weather exceedance events. See response to question 4 for information on how the load duration curves determine wet weather exceedance events. The QUAL-2K model assumes steady and non-uniform flow, which means that flow doesn't change over time. However, the QUAL-2K can be run under various flow conditions, for example, dry and wet condition, provided that the pollutant loads are available for these flow conditions. The representative wet weather flows can be used in QUAL-2K to evaluate how a waterbody responds to pollutant loads induced by stormwater runoff.

7. There was very limited data for manganese, with only two violations out of forty-five observations. One violation was extremely high indicating a possible faulty test. What efforts were taken after the sample was analyzed to ensure accuracy and reliability of the results? Are forty-five observations enough to be statistically significant?

Response

Illinois EPA did look at the manganese data for West Branch DuPage River (segment GBK-14) and found the extremely high data sample was magnesium which was then deleted from the dataset. There is still one exceedance of manganese which violates the water quality standard and requires a TMDL. According to the water quality standard for manganese, it is a toxic pollutant and one exceedance will result in a listing of impairment for a waterbody (refer to Table C-3 in the 2008 Integrated Report).

8. The DRSCW has monitored chlorides last year and these data shows more violations then Illinois EPA's data. Illinois EPA should include the chloride data in their assessment and in future modeling.

Response

Illinois EPA has received these data and will be using it as it applies to stream assessments and in the TMDL model.

9. The report does not state how it will account for naturally occurring phosphorus in the modeling. Illinois EPA should obtain the appropriate local data and perform the necessary studies that properly account for phosphorus as it naturally occurs in this watershed rather than basing it on non-comparable studies and assumptions.

Response

The only waterbody that we are doing a phosphorus TMDL on is Churchill Lagoon. Illinois EPA gives TMDL allocations to parameters with numeric water quality standards. Phosphorus as it applies to all lakes has a standard of 0.05 mg/L and takes into account background concentrations. As it turns out, there is a possibility that the dam might be removed for this waterbody. Therefore, the standard would not apply to this water and a TMDL would not be applied since no phosphorus standard has been adopted for streams. We will have more information in stage three of the TMDL process.

10. Instituting TMDLs, if done properly, should improve the water chemistry of our streams. However, they will do very little in improving the aquatic and wildlife habitat without making other improvements like streambank restorations, dam removals, wetland or riparian creation, etc. Instituting TMDLs will shift limited municipal resources towards compliance in meeting TMDL requirements, away from stream corridor improvements. This will have a substantial impact in our ability to make meaningful improvements to our lakes and streams.

Response

The outcome of TMDLs is allocations and can result in reductions from point sources and nonpoint sources. Through the NPDES permit program, the TMDL can reduce limits on point sources, but Illinois EPA does not have regulatory authority to make an entity or person apply nonpoint source Best Management Practices (BMPs) on their land. The TMDL recommends BMPs that can be established in the watershed to reduce pollutant loads and we recommend stakeholders begin watershed planning to see where it is feasible for BMPs to be installed. There are some watersheds that already have stakeholder groups formed (e.g., DRSCW) and are ready for planning to begin and there are other watersheds that use the TMDL to begin the process of planning. One tool the agency has is the 319 Nonpoint Source Program in which groups can get funding for watershed planning. There will be more information in the stage 3 implementation plan.

11. Page ES-1 reads, "Waterbodies included on the 303(d) list require Total Maximum Daily Load (TMDL) development." This statement is not entirely true. For example, an impaired water could be deemed to be impaired as the result of a natural cause, such as being classified into Category 4C.

Response

The 303(d) List is considered Category 5 in the Integrated Report. All Category 5 impairments require a TMDL. 4c is separate category and a TMDL will not be developed for these.

12. Should TSS and Sedimentation/siltation be included in Table 1-4, as no water quality standard criteria exist for those parameters?

Response

Yes, these parameters had TMDLs developed previously. The Agency no longer develops TMDLs for any parameter lacking a numeric standard. The Agency believes parameters with numeric standards have been through a rigorous approval process and wasteload allocations can apply.

13. While DuPage County recognizes the limited data complications present during this TMDL development process and how these pose difficulties in determining the geometric mean, the County has strong objection to changing the single sample maximum criterion (SSM) from 400 colony forming units (cfu) to 200 cfu. Making such a change would alter the risk level from 0.8% to approximately 0.55%. While

the proposed SSM criterion change is stated to be an implicit margin of safety (MOS), the change goes far beyond the MOS and completely changes the bacteria criterion against which the bacteria data are being assessed. A more appropriate reference to the implicit MOS would be to simply reference the load duration analysis itself, particularly that the percent reduction will be required from the greatest difference between recorded bacteria data and bacteria loads, calculated from flow data. The model should also provide calculated post-reduction daily bacteria levels, which would allow one to verify if the GM, theoretically, is being met.

Response

Illinois EPA is not changing the assessment methodology for fecal coliform. It is still assessed using the geometric mean of 200 cfu/100ml and a single sample maximum of 400 cfu/100ml. The allocations for NPDES wasteloads will be based on the permit limit of 400 cfu/100ml. If the facility is meeting their permit limit, no change will be required. We are required by USEPA to use the 200 cfu/100 ml for fecal coliform as the target load for the stream water quality. The post reduction bacteria levels are required to be under this target.

14. It is not clear to DuPage County why IEPA is pursuing a TMDL that includes the chloride, manganese, and silver parameters. Table C-3 in the IL 2008 Integrated Assessment (page 59) states that for toxic parameters, including these three, the "most recent consecutive three years of data are used." Looking at the data for the chloride and silver parameters, it is obvious that there are ten or more observations for each of the two parameters. Therefore, again referencing Table C-3, even a moderate impairment would require that two or more observations in the most recent consecutive three years of data exceed the applicable acute toxicity standard. Based on these data which indicate only one excursion in the applicable time period, the assessment units should not be impaired for chloride and silver and these parameters should not be included in the TMDL report.

Response

Chloride, manganese and silver are all three toxic parameters and one exceedance of the water quality standard indicates moderate impairment (refer to Table C-3 in the 2008 Integrated Report).

15. There are concerns over the way in which IEPA prioritizes its watersheds for TMDL development. While it is certainly important for public water supply areas to be addressed initially, the fact that IEPA bases prioritization on a sum of the total impairments with numerical criteria is questionable. More attention should be given to the available data (focusing on both quality and quantity of the data) and localized groups in the watershed seeking to enact the implementation plan included in a developed TMDL report rather than simply seeking to produce a report that includes all impairments for all assessment units within a single watershed. Again, single parameter TMDL reports should be considered if the existing data at the time of development are only sufficient enough for that particular parameter. Such a limitation allows for more focused analysis and implementation on that particular parameter for which a reliable TMDL report has been developed.

Response

As part of our prioritization effort, we are required to rank impaired waters by the severity of pollution. Severity of pollution is determined by summing the impairments in the waterbodies. The watersheds with more impairment were identified and listed with higher priority than those listed with fewer causes of impairment. Illinois EPA, along with many other states and following the recommendations of USEPA, develops TMDLs on a watershed basis. Implementation can take place on a single water segment or on a larger scale. Those decisions would be made by local stakeholders.

16. It does not seem logical that waste load allocations are going to be assigned for the phosphorus impairment at Churchill Lagoon. There are active plans to restore the lagoon into a free flowing stream, meaning that the phosphorus standard will no longer be applicable at this site. DuPage County

recommends that IEPA pursue moving that assessment unit into category 4B next assessment cycle, as measures taken will allow the waterway to meet applicable water quality standards within a reasonable period of time without the need for a TMDL report.

Response

As stated in the response to comment 9, if the lake standard for phosphorus will no longer be applicable to the waterbody, the TMDL will not proceed. The water will be assessed using the stream methodology.

17. Page 6-2 reads, "Stormwater dischargers are required to meet the percentage reduction or the existing instream standard for the pollutant of concern, whichever is less restrictive." Where is this requirement stated? References attached to statements such as this one would be appreciated.

Response

The statement is removed to the report since it is not applicable to the State of Illinois.

18. Page 1-8, Table 1-2. "Potential source(s)" of fecal coliform should include waterfowl. These animals have been shown to be significant sources of FC in lakes and streams (see *Characterization of E.coli Levels at 63rd Street Beach*, R. L. Whitman, et al, USGS, 2001 and *Effect of Waterfowl on Indicator Bacteria Populations in a Recreational Lake in Madison*, WI, J.H. Standridge, et al., Applied and Environmental Microbiology, September 1979). This is especially important in reach GBK-14 which has nearly stagnant flow during dry weather periods and is frequented by Canada Geese and other waterfowl. DNA fingerprinting of FC should be conducted in FC impaired reaches to determine if the impairment is from a human source, and if not, the impairment should be attributed to background conditions. If conducted following the TMDL, bacteria source tracking should precede any actions required to meet a wasteload allocation (WLA).

Response

Bacteria source tracking uses genetic and/or phenotypic test to identify bacteria strains that are host specific so that the host animal and source of the fecal contamination can be identified. The disadvantage is that a reference library of genetic or phenotypic fingerprints for bacteria isolated from known sources (sewage, livestock and wildlife) is needed to identify the sources. This is a very time consuming and expensive component of the study. Without a large reference library the tracking is very unreliable. Illinois EPA will not include source tracking in the TMDL process, but local stakeholders could use this as part of their watershed plans and/or implementation process.

19. Do all monitoring entities collecting data in the DuPage River/Salt Creek watershed have Quality Assurance Project Plans (QAPPs) and Standard Operating Procedures (SOPs) for their monitoring programs?

Response

Yes, data from DRSCW, Lake County Health Department, MWRGDC, Sierra Club, and Wheaton Sanitary District have QAPPs and SOPs. Data from these entities are used for water quality assessments and therefore require both.

20. What is meant by the phrase "....compliance was measured at the surface of the stream...?" Were all water quality constituents, including dissolved oxygen, measured at the surface? At what depth were the samples collected?

Response

Dissolved oxygen is measured at one foot below the surface of the water using a sonde unit probe. Water is collected for other parameters using a grab sample that is collected uniformly from the bottom to the top of the water.

21. Monitoring stations WW_109 and WW_21 in segment GL-19 are listed incorrectly on the map. The District does not have an ambient monitoring location identified as WW_21. Monitoring station WW_21 should be identified as WW_24 and is located at the point on the map where WW_109 is indicated. Monitoring station WW_24 is located where WW_21 is indicated.

Response

Illinois EPA used latitude and longitude information from the MWRDGC website. If these are incorrect, new location information needs to be obtained. Illinois EPA received data from MWRDGC with monitoring data for station WW_21 (Salt Creek at First Avenue) from January 2001 until April 2002. WW-24 (Salt Creek at Wolf Road) has data from January 2001 until May 2007. WW_109 (Salt at Brookfield Road) has data from July 2002 until May 2007.

22. TMDL segments need to be better defined. It is practically impossible to determine from the maps where the segments begin and end. Segments should be defined by geographical features or, preferably, latitude and longitude coordinates.

Response

Illinois EPA will be more specific in the final stage 1 draft report. Individual maps of each impaired segment will be included along with a table that includes latitude and longitude coordinates for each monitoring station.

23. Despite the fact that the Illinois EPA identified the West Branch DuPage River as impaired due to zinc concentrations, no TMDL will be developed for this pollutant. The text of the report does not discuss the issue of zinc impairment of the West Branch DuPage River. This issue is only addressed as a footnote to Table 1-1. Based upon the identification of zinc impairment, the Illinois EPA has begun to place zinc limits in NPDES permits for municipal plants discharging to this river including the Village of Hanover Park Sewage Treatment Plant. Without conducting the formal TMDL process for zinc, there can be no assurance that the Illinois EPA's strategy will eliminate zinc impairment of the West Branch DuPage River. After extensive sampling and investigation of zinc concentrations within the Hanover Park sewer service area, it has been determined that the domestic concentrations of zinc are nearly the same as the industrial discharge concentrations. The domestic sewage accounts for roughly 80% of the WWTP flow while industry discharge only accounts for 20%. Even if industry is limited to zero discharge of zinc, the effluent would not meet the monthly zinc effluent limit of 0.046 mg/L. The technology to remove zinc and the cost associated with such an upgrade are significant. There is a concern that scarce tax dollars will be spent on point source control of zinc without solving the impairment.

Response

Domestic and industrial discharges are both considered point sources. The NPDES program has been established for control of point source discharges. This program is relied upon for reductions if there are impairments only due to point sources.

24. There is a single exceedance of manganese for segment GBK-14. That exceedance occurs during a period of relatively high sampling (4 year period accounting for perhaps 30 of the sample points). It would be of interest to know what the flow rates were when the outlier was sampled and see what proportion of the samples were collected under similar flow regimes. With one exceedance, the parameter does not meet the guideline for an impairment set out in the 2008 Integrated Assessment Report. In addition, it is our information that the standard for manganese is being revised for the State of

Illinois. In our assessment with the new standard, there is no exceedance. The TMDL for this parameter should be suspended.

Response

According to our assessment methodology (2008 Integrated Report on page 59, Table C-3) for aquatic life designated use, a single exceedance violates the chronic toxic standard for manganese. Once this standard is violated, the water body is impaired. Illinois EPA is in the process of developing new manganese standards, but this is in the initial stages. The Illinois Pollution Control Board must review and approve any changes to water quality standards before they can be utilized in Illinois EPA water quality assessments. In regards to flow analysis, as part of the stage 3 development a load duration curve will be utilized and this takes into account flow at the time each sample was taken. This can determine the flow regime in which violations take place and sources that attribute at that flow regime.

25. The two exceedences for chloride do not meet the standards set out in the 2008 Integrated Report for an impairment. However, there is DRSCW data that shows multiple exceedences for multiple sites and violations were correlated to storms. In addition, the Bioassessment plan found TDS higher than 1000 mg/L in several tributaries during summer months; chloride is most likely the bulk of these dissolved ions. We are satisfied that chloride levels are exceeded across the program area during winter months but also in a more limited area, warm weather periods, and that the principle source is winter de-icing compounds. Since you had poor data and there are de-icing operation already underway in the upper DuPage and Salt, a TMDL should not be completed for chloride. It is unlikely that such a development will contain more detailed analysis or recommendations than the 2007 DRSCW Chloride Usage Education and Reduction Study which was a completed due to the chloride TMDL allocations on the West and East Branches of DuPage.

Response

Please refer to the response for comment 14. Chloride is also a toxic chemical and falls under the same assessment as manganese. As required by the Clean Water Act, Illinois EPA will develop a TMDL. As with manganese, load duration curves will be utilized for chloride. Illinois EPA will have information in the implementation plan on the de-icing program/ chloride reduction study.

26. The silver data presented do not meet the standard set out in the Integrated Report. The Bioassessment study looked at 19 sites of the West Branch DuPage and all sites exceeded threshold levels, but did not exceed the probably effects levels as did PCBs found in sediment. Silver may be a problem, but not a priority at this time.

Response

Please refer to the response for comment 14. Silver is also a toxic chemical and falls under the same assessment protocol as manganese. Illinois EPA will not be developing a TMDL for PCBs in sediment as there are no standards for this parameter in sediment.

27. While agriculture may be an important source of nutrient loading, in terms of the Upper DuPage and Salt Creek the small proportion of the area with agriculture use means its effect should not be exaggerated. A more important source of nutrient loading is residential landscaping areas that are the dominant land use management practice in the areas and may produce up to 41% of the NPS phosphorus loadings in tributary watersheds (loadings in tributary watersheds Upper DuPage River Watershed Plan Update). This land use is ignored in chapter 5.3.

Response

While the Salt Creek watershed has only twelve percent agriculture land use, the DuPage River as over twenty percent. Residential areas are not ignored in the analysis. Urban Low/Medium Density which

represents residential areas comprise 30 percent in the DuPage River watershed and almost 47 percent in Salt Creek watershed.

28. Non-point source impairments are strong concerns for the ultimate health of the watershed. Wastewater plants in the region have already reached the point of cost effective treatment for these parameters. Significant investment in wastewater treatment will produce minimal benefit to the watershed. If additional improvements are required at wastewater plants, their carbon footprints are likely to increase thereby adversely affecting the quality of air in the region. We would highly encourage focusing on non-point sources.

Response

The TMDL will focus on all sources of pollutants and Illinois EPA is required to have allocations for both point and non-point sources in the watershed.

29. There has been substantial modification of the cross section of the West Branch of the DuPage River over the last few years, and additional modifications are anticipated over the next two or three years. During construction, the entire river flow is pumped around the construction site. It is well documented that when the water is inside pipes, organics remove DO from the water. This means that lower than normal DO levels should be occurring in the River whenever bypass pumping is being conducted on the River. In addition, a multi-year thorium removal project is expected to require two or three more years to complete. As a result, DO sampling of the river during this period will not be representative of the River's natural DO level after the work has been completed. IN addition, the dam in McDowell Woods Forest Preserve was removed in fall of 2008, and the dam in Warrenville is scheduled for removal in 2009. Removal of the dams is expected to increase DO levels in the previously impounded sections as well as downstream.

Response:

Regular monitoring of these waterways will continue and this includes DO. Assessment of the results should help focus the need and nature of any BMPs needed.

30. Based on a recent study on Salt Creek, significant phosphorus reductions in the Egan Plant's effluent did not have a measurable impact on either the algae biomass or DO. Egan supplies approximately 50% of the effluent received by Salt Creek. Studies have found a very strong correlation between habitat and diversity in fish and macro-invertebrate populations, suggesting that, at this time, habitat is the primary limiter in our streams and rivers. Therefore, we believe that a focus on habitat, rather than phosphorus removal, would be the most cost effective approach for improving aquatic life in local waterways.

Response:

As we are only in the water characterization stage, Illinois EPA has not done a source analysis. The stage 3 modeling will look at the permitted facilities and see if reductions need to be made by nonpoint and/or point sources. The TMDL Implementation Plan will be utilizing the biological study that was developed for this watershed and habitat improvement BMPs (best management practices) will be discussed.

31. Copper was identified as a municipal point source impairment for Spring Brook. We must ask that this be removed. Effluent sampling from the municipal point source that discharges to it does not show impairment. Please note that the January 4, 2006 data point was off by a factor of 10. That datum should have been recorded as 0.011 mg/L instead of 0.11 mg/L.

Response:

The municipal point source provided data for this assessment and the correction was made for the sampling data for January 4, 2006. According to these data, there was a sample from July 6, 2005 that

exceeded the chronic standard of 0.020 mg/L. According to our copper standard, this exceedance indicates moderate impairment in the stream.

32. Does the regular dissolved oxygen standard apply to all waters or does the enhanced protection standard apply to some of the waters in this watershed?

Response:

Language has been added to the report on waters with enhanced dissolved oxygen protection. Basically DuPage River segments GB-11, GB-16 and West Branch DuPage River segment GBK-02 are waters with enhanced protection for dissolved oxygen. These waters were assessed using the more stringent enhanced protection standard. Segment GB-16 is the only segment that is impaired for dissolved oxygen according to the enhanced protection standard.

THIS PAGE INTENTIONALLY LEFT BLANK

Section 1 Introduction

The Illinois Environmental Protection Agency (Illinois EPA) has a three-stage approach to total maximum daily load (TMDL) development. The stages are:

Stage 1 - Watershed Characterization, Data Analysis, Methodology Selection

Stage 2 – Data Collection (optional)

Stage 3 - Model Calibration, TMDL Scenarios, Implementation Plan

This report addresses data collection associated with Stage 2 TMDL development for the Salt Creek/DuPage River watershed. Stage 1 has been completed by ENSR and is available for review at: <u>http://www.epa.state.il.us/water/tmdl/report-status.html</u>.

Sediment oxygen demand (SOD) monitoring was completed based on the recommendations presented in Section 6 of the Stage 1 TMDL report. The Stage 2 data will supplement existing data collected and assessed as part of Stage 1 of TMDL development and will support the development of TMDLs under Stage 3 of the process. SOD monitoring was recommended to lend confidence to dissolved oxygen modeling.

The remaining sections of this report contain:

- Section 2 Field Activities includes information on sampling locations as well as methodology and field measurements
- Section 3 Data Analysis and Results presents the collected data and formulas used to determine SOD rates

Section 1 Introduction

Section 2 Field Activities

2.1 Sampling Locations

The West Branch DuPage River and mainstem DuPage River were sampled by CDM during the fall of 2009 to collect data needed to support water quality modeling and TMDL development. Five sites (see Figure 2-1) were selected based on model reaches identified by ENSR during Stage 1 of TMDL development along with stakeholder input, accessibility, and streambed composition. The West Branch DuPage River sites were monitored in late August and the mainstem site was monitored in late September. Table 2-1 contains site location information and data collection dates. Sampling was conducted in accordance with the QAPP by CDM personnel at each of the below locations. The mainstem monitoring at Naperville was postponed until September 27 due to elevated stream flows and access issues the week of August 25. Photographs from each site are available at the end of this section.

Table 2-1. Staye 2 Data Coll	ection Siles and Field Dates)
Monitoring Location	Monitoring Date (2009)	Stream Location
Hanover Park	8/25	Approximately 50 feet upstream of WWTP discharge
West Chicago	8/25	100 yards upstream of WWTP discharge
McDowell Forest Preserve	8/26	200 feet upstream of dam
Knoch Knolls Park	8/26	300 yards downstream of parking lot
Naperville	9/27	100 yards upstream of WWTP discharge

Table 2-1: Stage 2 Data Collection Sites and Field Dates

2.2 Methodology

SOD testing was performed during periods of low-flow at five wadeable sites on the West Branch and mainstem DuPage River. Prior to sampling, three SOD chambers were constructed by CDM for use in the field. CDM designed and built the chambers using the Murphy and Hicks (1986) reference as guidance. Figure 2-2 shows the Murphy and Hicks chamber diagram used for design purposes and a graphic representation of CDM's constructed chambers. Figure 2-3 shows a photograph of the actual chambers deployed for this sampling event. The SOD chambers were constructed out of heavy plastic 55-gallon drums that were sized down and left with a cutting edge for the live chambers and capped with an air-tight seal for the blank chamber. Bilge pumps hooked up to a car battery and plastic tubing were used to circulate water through the chambers. A hole with an air-tight seal was left in the top of each chamber to accommodate water quality measurement instruments. In-situ Inc. 9055 Professional Trolls were used for this sampling event.

All three chambers were deployed at each site in areas with suitable sediment, from downstream to upstream . Once in place, the chambers were left for a minimum of 15 minutes so that any suspended sediments could settle before measurements were started. Chamber flow recirculation was established using the pumps to approximately

mimic stream bottom flows. A multi-parameter water quality meter was used to take chamber measurements. DO and temperature measurements were logged at 1- minute intervals over at least an hour and a half. While the tests were proceeding, the water quality monitors were regularly checked to monitor test validity.

Simultaneously, a dark bottle filled with ambient bottom water was deployed for incubation during the course of the SOD experiments. The water column respiration values obtained from the dark bottles were recorded in the field book and were measured as an available back up to blank chamber experiments in case of chamber failure.

Section 3 Data Analysis and Results

3.1 Data Analysis

As discussed in Section 2, water quality data were logged with In-Situ, Inc 9055 Professional Trolls. In-Situ, Inc software was used to download the files which were then transferred to Microsoft Excel. Data files are available in Appendix A. Dissolved oxygen data were plotted versus time to determine a rate of change of DO concentrations in each of the chambers. Figures 3-1 through 3-5 show the plotted data used for calculations at each site (refer to Figure 2-1 for sampling location information).

Figure 3-1 DO Data Collected at Hanover Park on 8/25/09

Figure 3-3 DO Data Collected at McDowell Forest Preserve on 8/26/09

Figure 3-4 DO Data Collected at Knock Knolls on 8/26/09

Figure 3-5 DO Data Collected at Naperville on 9/29/09

As shown in Figure 3-1, only a portion of the data collected from sediment chamber 1 was used for SOD calculations. Manual checks of the DO readings in the field indicated that sediment chamber 1 was not operating properly (all field notes are available in Appendix B). Adjustments were made during the test to reset the chamber and probe. Data that were logged after these field adjustments were used for calculations.

As shown in Figures 3-4 and 3-5, data from sediment chamber 2 were thrown out due to erratic DO readings throughout the monitoring.

Downloaded data from each site were then used to calculate SOD rates using the following equation:

 $SOD = (V/A) \times (b_1 - b_2) / 1000$

Where SOD = sediment oxygen demand rate (grams/meter²/day) b_1 = rate of change of DO concentration in the SOD chamber (milligram/Liter/day) b_2 = rate of change of DO concentration in the blank chamber (milligram/Liter/day) V = volume of the chamber (Liters) A = area of the chamber (meter²)

When data were available from both sediment chambers, the average rate of change was used for calculating SOD rates. Each blank chamber functioned properly, therefore dark bottle readings were not needed for backup. The dark bottle readings are available in the field notes found in Appendix B.

SOD data were then adjusted to a base water temperature of 20 degrees C for reporting purposes. The Arhenius temperature equation was used to adjust rates to a 20 degrees C ambient water temperature.

 $\begin{aligned} &\text{SOD}(t) = \text{SOD}(20) \ge \Theta^{(\text{T-}20)}\\ &\text{SOD}(20) = \text{SOD}(t)/\Theta^{(\text{T-}20)} \end{aligned}$

Where SOD(t) = sediment oxygen demand at temperature T SOD(20) = sediment oxygen demand at temperature 20 degrees C Θ = temperature correction coefficient, 1.08

3.2 Data Results

Table 3-1 contains the data used for calculation at each site and the calculated SOD rates. Differences between calculated SOD rates for both sediment chambers varied only slightly at Hanover Park and McDowell Forest Preserve. The West Chicago site had a larger difference which may indicate varied sediment composition at the site. Again, averages were used when both sediment chambers' data were available.

 Table 3-1: Data used for calculation and calculated SOD rates

* Data not used due to chamber failure Volume (L) = 58.3282Area (m²) = 0.25688

As shown in Table 3-1 above, SOD rates at ambient temperatures ranged from 2.45 g/m²/day at Hanover Park (the upstream sampling location on the West Branch DuPage River) to 6.19 g/m²/day at West Chicago. When temperature were corrected to 20 degrees C, rates increased from upstream (2.04 g/m²/day at Hanover Park on the West Branch DuPage Rive) to downstream (5.58 g/m²/day at Naperville on the mainstem DuPage River).

Previous SOD monitoring conducted in 2008 on the East Branch DuPage River yielded results that ranged from 1.13 to 3.61 $g/m^2/day$. This sampling effort indicates that SOD rates are higher on the West Branch than on the East Branch. Because SOD is the sum of all biological and chemical processes in sediment that utilize oxygen, this could mean that the West Branch has more anaerobic (low-oxygen) chemical compounds in the sediments and particulate biological oxygen demand (BOD) (including algae and other sources of organic matter) settling out of the water column.

Appendix A SOD Monitoring Data

Hanover Park Sediment Probe 1

Hanover Park Sediment Probe 2

In-Situ Inc.	Troll 9000 Pro X	(P
Report generated: Report from file: Win-Situ® Version	8/27/2009 \SN48193 200 4.58.14.0	13:24:43)9-08-25 115145 sod5-1.bin
Serial number: Firmware Version Unit name:	2110	
Test name:	SO	d5-1
Test defined on: Test started on: Test stopped on:	8/25/2009	11:51:45
Data gathered using Linear testing Time between data points: 60.0 Number of data samples:	Seconds.	

143

In-Situ Inc. Troll 9000 Pro XP

Report generated: 8/27/2009 13:57:01 Report from file: ...\SN48381 2009-08-25 162103 wchicago-sed1.bin

111

Win-Situ® Version 4.58.14.0

Serial number: Firmware Version Unit name:	48381 2.13 MP Troll 9000	
Test name:		wchicago-sed1
Test defined on: Test started on:	8/25/2009 8/25/2009	16:20:53 16:21:03
Test stopped on: Data gathered	8/25/2009	18:11:41

Data gathered using Linear testing Time between data points: 60.0 Number of data samples: Seconds.

In-Situ Inc. Troll 9000 Pro XP

Report generated: 8/27/2009 13:28:47 Report from file: ...\SN48193 2009-08-25 162324 wchicago-s2.bin

Win-Situ® Version 4.58.14.0

Serial number: Firmware Version Unit name:	48193 2.13 MP Troll 9000	
Test name:		wchicago-s2
Test defined on: Test started on: Test stopped on:	8/25/2009 8/25/2009 8/25/2009	16:23:24
Data gathered using Linear testing Time between data points: 60.0 Number of data samples:	Seconds.

West Chicago Blank Chamber

In-Situ Inc. Troll 9000 Pro XP

13:47:55 8/27/2009 Report generated: 33 wchicago-blank.bin

Report from file: Win-Situ® Version	\SN48396 2009- 4.58.14.0	08-25 151833 wc
Serial number: Firmware Version Unit name:	48396 2.13 MP Troll 9000	
Test name:		wchicago-blank
Test defined on: Test started on: Test stopped on:	8/25/2009 8/25/2009 8/25/2009	15:18:33
Data gathered using Linear testing Time between data points: 60.0 Number of data	Seconds.	
samples:	117

Knock Knolls Sediment Probe 1

In-Situ Inc.	Troll 9000 Pro XP										
Report generated: Report from file: Win-Situ® Version		13:58:31 -08-26 141802 sod	4-knoch-sed1.	bin							
Serial number: Firmware Version Unit name:	48381 2.13 MP Troll 9000										
Test name:		sod4-knoch-sed1									
Test defined on: Test started on: Test stopped on:	8/26/2009 8/26/2009 8/26/2009	14:17:55 14:18:02 17:10:51									
Data gathered using Linear testing Time between data points: 60.0 Number of data samples:	Seconds. 173

In-Situ Inc.	Troll 9000 Pro	ХР									
Report generated: Report from file: Win-Situ®	9/30/2009 \SN48194 20		104415 sed-2.k	bin							
Version	4.58.14.0										
	10101										
Serial number: Firmware Version											
Unit name:	MP Troll 9000										
Test name:		sed-2									
Test defined on:	9/29/2009	10:43:33									
Test started on:	9/29/2009										
Test stopped on:	9/29/2009	13:51:32									
Data gathered using Linear testing Time between											
data points: 60.0	Seconds.										
Number of	Seconds.										
data samples:	188

THIS PAGE INTENTIONALLY LEFT BLANK

Location Du Page River Date 7-16-09 Project/Client SOD Sampling - Site visit

1400 - On site (SOD-S) Hanover Park on W. Du Page river Site accessed From WWTP or Arlington Rd. - Easter access from WWTP- Ask permission but can be reached through riparica buffer From Arlington road - Stream shallow - Z Ft max, appears to be soft sedment with some debas · duent Flow, steep banks, turbid. 2 Photos -From 5 bonk new Bolington Road, - Upstream, substrate. Approx 75yrds Up from WWTP fence Note - bont not likely to be needed or usable at this site -Additional access upstream at Arlington Red bridge 2 Photos from bridge - downstream, substrate 1420 - Attempting to access (SOD-4) - Bartlett No access except through WWTP, observed stream. From upstream approx Emile. Flows through large grassland/pasture. Perent flow, soft sed.mentsbooks less steep than SUDS. I photo of WWTP access. Bont questionable for this location

49

Location U Dr Page River Date 8-16-09 Project/Client Sop Sampling - Site Visite

1945- on site SOD-5 - West Chicago. Easiest access from WWTP, can be reached From bridge downstream at Rassevelt Rd and possibly from park off Rt 59, " Stream considerably wider - Soft estimate, 2-3 ft deep, mixed fine sediment and debris, rock. Sed inent tayer appears to be mostly shallow, mining in-stream structure, - Access From Recsevelt includes di Hicult banks and parking. Bents strep and heavily vegetated 3 photos - Upstrown, discharge, substrate. -Note: Discharge appears to be from Pipe near Recoverelt Bridge. 1500 -Acuss print to SOD-3 From Forest Preservo parking area approx. O.2 miles upstream. "Verld require 0.1 mile walk. - Bont call be used, but not necessary at location 1520 - On site (SOD-2) - Acdovell Forest Proverve. Sile easily accessible - Park Area, Area upstream of bridge backed up, wide, some macrophytes, Small dan over Flow below bridge. Bont could be used and may be helpful at this site. Photos: 4 - Down, Up, Sub, Upstrong Site very furbid, had to gauge depth visually

Location W, DV Page River Date 7-16-09 Project/Client SOD Sampling - Site Visil-

1550 - SOD-Z site will most likely have nit of substrate with fines in deeper part of pool - Depth may be an issue here, Recommend upstran of bridge due to small drop off below and re-acration possible, 1600 - On site BOD -1) - Naperville - Knock Knolls Park - Point appears to be completely inaccessible. Park access approx 0.5 m.7.5 upstream. Pessible to Float down to site or may be private property sccess, Visited site from upstream park 3 phatos- down, sub, spatrown Stroom wide - SO-75', shallow 1-2 Ft. More natural backs, probably more gravel and copple substrate - my be reason for down stron- also this is still the W. Branch. Seat possible if shallow draft. 1620 - Offsite SOD-1 7-16-09

2 Location W. Du Rage River Date 8/25/09 Project / Client SOD Sampling

0815 - On site Forest Preserve Grounds and Resources office to meet with Steve Mckracken of the resource group. Crevi B. Bennett (author), D. Irrdan, B. Dunavant Weather: Sunny 85°F high Forcast Tasks for the day: Discuss locations + access with S. Mc Kreeker, begin sompling at upstream - most site (sob-5). 0835 - S. McKrecken arrives - begin discussing site locations. Talks with Jenny Clark about replacing battett location with one on Moinsten DuRage. J. Clark confirmed that original list may be altered 0940 in route to Hanover Park site 1000 - On site Hanaver Tark WRP. Met with Lorry Stehl - plant supervisor to get access to river Easy access from parking area 1005 - Begin unleading equipment 1113- Check meters w stream water Sediment & DO-8.03 blank DO-7.96 sediment 1 00 - 7.93 GA/QC DO- 8.05 @ 1:25 = 7.32 Location _____ Project / Client

Public Comments and Responsiveness Summary

Stage One Responsiveness Summary

This responsiveness summary responds to substantive questions and comments received during the public comment period from January 16, 2009 through April 17, 2009 postmarked, including those from the January 28, 2009 public meeting discussed below.

What is a TMDL?

A Total Maximum Daily Load (TMDL) is the sum of the allowable amount of a pollutant that a water body can receive from all contributing sources and still meet water quality standards or designated uses. This TMDL is for the DuPage River/Salt Creek watersheds. In Illinois, developing a TMDL is a three stage process and this is a stage one report which contains the watershed characteristics, impairments and potential sources. After the stage one report, stage two and stage three will proceed. Stage two would include additional monitoring and stage three is the required modeling, allocations and reductions for each TMDL impairment and would also include an implementation plan.

Background

The DuPage River and Salt Creek watersheds drain approximately 332,600 acres and lies mainly in Cook, DuPage and Will counties. Land use in the DuPage River watershed is 65% urban, 21% agriculture and 10% forest while in Salt Creek it is 85% urban and 12% forest. Waters impaired in this watershed are DuPage River, East Branch DuPage, West Branch DuPage, Spring Brook, Salt Creek, Addison Creek and Churchill Lagoon. The DuPage River is listed on the Illinois EPA 2008 Section 303(d) List as being impaired for chloride, fecal coliform, dissolved oxygen and silver. East Branch is impaired for fecal coliform and pH. West Branch is impaired for dissolved oxygen, fecal coliform, silver, manganese and pH. Spring Brook is impaired for dissolved oxygen and fecal coliform. Salt Creek is impaired for fecal coliform and pH. Churchill Lagoon is impaired for phosphorus. The Clean Water Act and USEPA regulations require that states develop TMDLs for waters on the Section 303(d) List. Illinois EPA develops TMDLs allocations for impairments with numeric water quality standards, but some non-numeric standards may be addressed through the implementation plan. Best Management Practices (BMPs) put in place for TMDL impairments may reduce other parameters associated with it.

Public Meetings

A stage one public meeting was held in Elmhurst on January 28, 2009. The Illinois EPA provided public notices for all meetings by placing an ad in the local newspapers in the watershed; the Chicago Daily Herald, The Will-South DuPage Report and the Central Cook Suburban. These notices gave the date, time, location, and purpose of the meetings. It also provided references to obtain additional information about this specific site, the TMDL Program and other related issues. Individuals and organizations were also sent the public notice by first class mail. An additional stakeholder meeting was held March 31, 2009 in Plainfield, IL. The draft TMDL Report was available for review at the Elmhurst City Hall and on the Agency's web page at http://www.epa.state.il.us/water/tmdl.

The first public meeting on January 28, 2009 started at 6:00 p.m. and was attended by approximately 50 people. The second stakeholder meeting on March 31, 2009, started at 10:00 am and was attended by 20 people. The meeting record remained open until midnight, April 17, 2009.

There will be a public meeting for the stage three TMDL report in the future and a responsiveness summary will be developed for this meeting also.

Questions and Comments

1. The stakeholders in the watershed were not given the opportunity to provide input on how the stage 1 report was to be conducted. Many of the same issues discovered in the first TMDLs are also appearing in this report. Why were we not given the opportunity to provide input in the early stages of planning and conducting the report?

Response

The Illinois EPA published the Illinois Integrated Water Quality Report and Section 303(d) List- 2006 in June of 2006. This document lists all the waters for TMDL development in the next two years. All of the segments for this TMDL were listed in Table C-29 of the Integrated Report. The Illinois EPA holds the first public meeting at the beginning of the TMDL process- in stage one. The basic watershed information is completed in this stage and presented to the public. This is also the stage we request any other relevant data in the watershed and public input. Illinois EPA also participates in the DuPage River Salt Creek Workgroup and keeps the Workgroup updated on TMDL issues.

2. The water quality standard for fecal coliform is "based on a minimum five samples taken over a 30 day period". However, Illinois EPA does not have the appropriate number of samples and therefore has elected to use an alternative water quality standard. Illinois EPA should obtain the necessary data to use the more preferred standard for assessment purposes.

Response

Illinois EPA does sample at the frequency required by one part of the standard. Stations that are assessed for primary contact in this watershed are sampled approximately monthly. If available, five years of data are used for the primary contact assessments. For this TMDL, most of the assessments were based on data that were received from outside sources. From those stations sampled by outside sources, Illinois EPA will accept sampling at the correct frequency when the standard is applied- May through October. If their data become available this year, they will be used for the TMDL. The DRSC Workgroup is developing a sampling plan for this watershed as part of the implementation process.

3. The report does not state how the effect of animals on fecal coliform will be addressed. Illinois EPA stated in the public meeting that they would try to use some data that have been gathered in other states but the data may not be comparable to this watershed and therefore assumptions may have to be made. This will greatly decrease the reliability of the modeling and ultimately the wasteload allocations and TMDL. Therefore, it is imperative that Illinois EPA obtain the appropriate data and perform the necessary studies to properly account for the effect of wildlife on fecal coliform.

Response

Illinois EPA will be addressing the bacteria impairments using the load duration curve analysis. Bacteria data and flow data are the basis of this analysis. Loads are ranked per flow and one can which flow periods in which there are exceedences of fecal coliform bacteria. By using this approach, sources can be tracked by the flow period. For example, if point sources are causing the majority of the problem, exceedences will be seen even in low flow periods when there is no precipitation causing runoff. If the main problem is runoff related, exceedences will be seen in high and medium flow periods only. The analysis also shows the exceedences that are due to storm flows. Exceedences due to wildlife would be expected in high to high-medium flows. Illinois EPA is not aware of any livestock facilities in this watershed and does not have adequate estimates of wildlife populations in this area. If anyone is aware of these data, Illinois EPA would like to obtain this information.

4. Through studies performed by DRSCW, it has been clearly shown that sediment oxygen demand (SOD) has a profound effect on the QUAL-2K model for DO. This model is very sensitive to SOD and therefore SOD monitoring data are critical when modeling for DO. Illinois EPA must obtain the required SOD data in order to properly perform water quality modeling for DO.

Response

In response to suggestions made at the Stage One Public Meeting, Illinois EPA will be obtaining SOD samples from the West Branch DuPage River.

5. Illinois EPA is going to use monthly monitoring reports from publicly owned treatment works (POTWs) to provide data for the QUAL-2K model when studying the DO parameter. However, Illinois EPA should use actual data that are readily available.

Response

Illinois EPA typically uses the designed average flow (DAF) for NPDES facilities discharging in the watershed. It was brought to our attention at the meeting that this may over-estimate loads from these sources and flow data obtained from the individual facilities would best represent loads in the model. NPDES facilities are not required to give Illinois EPA this flow information, but Illinois EPA will work with facilities to obtain it.

6. The Report does not state how it will address wet weather flow. Illinois EPA should obtain the necessary wet weather data to determine how they are going to address wet weather flows.

Response

See response to question 4 for information on how the load duration curves determine wet weather exceedance events. See response to question 4 for information on how the load duration curves determine wet weather exceedance events. The QUAL-2K model assumes steady and non-uniform flow, which means that flow doesn't change over time. However, the QUAL-2K can be run under various flow conditions, for example, dry and wet condition, provided that the pollutant loads are available for these flow conditions. The representative wet weather flows can be used in QUAL-2K to evaluate how a waterbody responds to pollutant loads induced by stormwater runoff.

7. There was very limited data for manganese, with only two violations out of forty-five observations. One violation was extremely high indicating a possible faulty test. What efforts were taken after the sample was analyzed to ensure accuracy and reliability of the results? Are forty-five observations enough to be statistically significant?

Response

Illinois EPA did look at the manganese data for West Branch DuPage River (segment GBK-14) and found the extremely high data sample was magnesium which was then deleted from the dataset. There is still one exceedance of manganese which violates the water quality standard and requires a TMDL. According to the water quality standard for manganese, it is a toxic pollutant and one exceedance will result in a listing of impairment for a waterbody (refer to Table C-3 in the 2008 Integrated Report).

8. The DRSCW has monitored chlorides last year and these data shows more violations then Illinois EPA's data. Illinois EPA should include the chloride data in their assessment and in future modeling.

Response

Illinois EPA has received these data and will be using it as it applies to stream assessments and in the TMDL model.

9. The report does not state how it will account for naturally occurring phosphorus in the modeling. Illinois EPA should obtain the appropriate local data and perform the necessary studies that properly account for phosphorus as it naturally occurs in this watershed rather than basing it on non-comparable studies and assumptions.

Response

The only waterbody that we are doing a phosphorus TMDL on is Churchill Lagoon. Illinois EPA gives TMDL allocations to parameters with numeric water quality standards. Phosphorus as it applies to all lakes has a standard of 0.05 mg/L and takes into account background concentrations. As it turns out, there is a possibility that the dam might be removed for this waterbody. Therefore, the standard would not apply to this water and a TMDL would not be applied since no phosphorus standard has been adopted for streams. We will have more information in stage three of the TMDL process.

10. Instituting TMDLs, if done properly, should improve the water chemistry of our streams. However, they will do very little in improving the aquatic and wildlife habitat without making other improvements like streambank restorations, dam removals, wetland or riparian creation, etc. Instituting TMDLs will shift limited municipal resources towards compliance in meeting TMDL requirements, away from stream corridor improvements. This will have a substantial impact in our ability to make meaningful improvements to our lakes and streams.

Response

The outcome of TMDLs is allocations and can result in reductions from point sources and nonpoint sources. Through the NPDES permit program, the TMDL can reduce limits on point sources, but Illinois EPA does not have regulatory authority to make an entity or person apply nonpoint source Best Management Practices (BMPs) on their land. The TMDL recommends BMPs that can be established in the watershed to reduce pollutant loads and we recommend stakeholders begin watershed planning to see where it is feasible for BMPs to be installed. There are some watersheds that already have stakeholder groups formed (e.g., DRSCW) and are ready for planning to begin and there are other watersheds that use the TMDL to begin the process of planning. One tool the agency has is the 319 Nonpoint Source Program in which groups can get funding for watershed planning. There will be more information in the stage 3 implementation plan.

11. Page ES-1 reads, "Waterbodies included on the 303(d) list require Total Maximum Daily Load (TMDL) development." This statement is not entirely true. For example, an impaired water could be deemed to be impaired as the result of a natural cause, such as being classified into Category 4C.

Response

The 303(d) List is considered Category 5 in the Integrated Report. All Category 5 impairments require a TMDL. 4c is separate category and a TMDL will not be developed for these.

12. Should TSS and Sedimentation/siltation be included in Table 1-4, as no water quality standard criteria exist for those parameters?

Response

Yes, these parameters had TMDLs developed previously. The Agency no longer develops TMDLs for any parameter lacking a numeric standard. The Agency believes parameters with numeric standards have been through a rigorous approval process and wasteload allocations can apply.

13. While DuPage County recognizes the limited data complications present during this TMDL development process and how these pose difficulties in determining the geometric mean, the County has strong objection to changing the single sample maximum criterion (SSM) from 400 colony forming units (cfu) to 200 cfu. Making such a change would alter the risk level from 0.8% to approximately 0.55%. While

the proposed SSM criterion change is stated to be an implicit margin of safety (MOS), the change goes far beyond the MOS and completely changes the bacteria criterion against which the bacteria data are being assessed. A more appropriate reference to the implicit MOS would be to simply reference the load duration analysis itself, particularly that the percent reduction will be required from the greatest difference between recorded bacteria data and bacteria loads, calculated from flow data. The model should also provide calculated post-reduction daily bacteria levels, which would allow one to verify if the GM, theoretically, is being met.

Response

Illinois EPA is not changing the assessment methodology for fecal coliform. It is still assessed using the geometric mean of 200 cfu/100ml and a single sample maximum of 400 cfu/100ml. The allocations for NPDES wasteloads will be based on the permit limit of 400 cfu/100ml. If the facility is meeting their permit limit, no change will be required. We are required by USEPA to use the 200 cfu/100 ml for fecal coliform as the target load for the stream water quality. The post reduction bacteria levels are required to be under this target.

14. It is not clear to DuPage County why IEPA is pursuing a TMDL that includes the chloride, manganese, and silver parameters. Table C-3 in the IL 2008 Integrated Assessment (page 59) states that for toxic parameters, including these three, the "most recent consecutive three years of data are used." Looking at the data for the chloride and silver parameters, it is obvious that there are ten or more observations for each of the two parameters. Therefore, again referencing Table C-3, even a moderate impairment would require that two or more observations in the most recent consecutive three years of data exceed the applicable acute toxicity standard. Based on these data which indicate only one excursion in the applicable time period, the assessment units should not be impaired for chloride and silver and these parameters should not be included in the TMDL report.

Response

Chloride, manganese and silver are all three toxic parameters and one exceedance of the water quality standard indicates moderate impairment (refer to Table C-3 in the 2008 Integrated Report).

15. There are concerns over the way in which IEPA prioritizes its watersheds for TMDL development. While it is certainly important for public water supply areas to be addressed initially, the fact that IEPA bases prioritization on a sum of the total impairments with numerical criteria is questionable. More attention should be given to the available data (focusing on both quality and quantity of the data) and localized groups in the watershed seeking to enact the implementation plan included in a developed TMDL report rather than simply seeking to produce a report that includes all impairments for all assessment units within a single watershed. Again, single parameter TMDL reports should be considered if the existing data at the time of development are only sufficient enough for that particular parameter. Such a limitation allows for more focused analysis and implementation on that particular parameter for which a reliable TMDL report has been developed.

Response

As part of our prioritization effort, we are required to rank impaired waters by the severity of pollution. Severity of pollution is determined by summing the impairments in the waterbodies. The watersheds with more impairment were identified and listed with higher priority than those listed with fewer causes of impairment. Illinois EPA, along with many other states and following the recommendations of USEPA, develops TMDLs on a watershed basis. Implementation can take place on a single water segment or on a larger scale. Those decisions would be made by local stakeholders.

16. It does not seem logical that waste load allocations are going to be assigned for the phosphorus impairment at Churchill Lagoon. There are active plans to restore the lagoon into a free flowing stream, meaning that the phosphorus standard will no longer be applicable at this site. DuPage County

recommends that IEPA pursue moving that assessment unit into category 4B next assessment cycle, as measures taken will allow the waterway to meet applicable water quality standards within a reasonable period of time without the need for a TMDL report.

Response

As stated in the response to comment 9, if the lake standard for phosphorus will no longer be applicable to the waterbody, the TMDL will not proceed. The water will be assessed using the stream methodology.

17. Page 6-2 reads, "Stormwater dischargers are required to meet the percentage reduction or the existing instream standard for the pollutant of concern, whichever is less restrictive." Where is this requirement stated? References attached to statements such as this one would be appreciated.

Response

The statement is removed to the report since it is not applicable to the State of Illinois.

18. Page 1-8, Table 1-2. "Potential source(s)" of fecal coliform should include waterfowl. These animals have been shown to be significant sources of FC in lakes and streams (see *Characterization of E.coli Levels at 63rd Street Beach*, R. L. Whitman, et al, USGS, 2001 and *Effect of Waterfowl on Indicator Bacteria Populations in a Recreational Lake in Madison*, WI, J.H. Standridge, et al., Applied and Environmental Microbiology, September 1979). This is especially important in reach GBK-14 which has nearly stagnant flow during dry weather periods and is frequented by Canada Geese and other waterfowl. DNA fingerprinting of FC should be conducted in FC impaired reaches to determine if the impairment is from a human source, and if not, the impairment should be attributed to background conditions. If conducted following the TMDL, bacteria source tracking should precede any actions required to meet a wasteload allocation (WLA).

Response

Bacteria source tracking uses genetic and/or phenotypic test to identify bacteria strains that are host specific so that the host animal and source of the fecal contamination can be identified. The disadvantage is that a reference library of genetic or phenotypic fingerprints for bacteria isolated from known sources (sewage, livestock and wildlife) is needed to identify the sources. This is a very time consuming and expensive component of the study. Without a large reference library the tracking is very unreliable. Illinois EPA will not include source tracking in the TMDL process, but local stakeholders could use this as part of their watershed plans and/or implementation process.

19. Do all monitoring entities collecting data in the DuPage River/Salt Creek watershed have Quality Assurance Project Plans (QAPPs) and Standard Operating Procedures (SOPs) for their monitoring programs?

Response

Yes, data from DRSCW, Lake County Health Department, MWRGDC, Sierra Club, and Wheaton Sanitary District have QAPPs and SOPs. Data from these entities are used for water quality assessments and therefore require both.

20. What is meant by the phrase "....compliance was measured at the surface of the stream...?" Were all water quality constituents, including dissolved oxygen, measured at the surface? At what depth were the samples collected?

Response

Dissolved oxygen is measured at one foot below the surface of the water using a sonde unit probe. Water is collected for other parameters using a grab sample that is collected uniformly from the bottom to the top of the water.

21. Monitoring stations WW_109 and WW_21 in segment GL-19 are listed incorrectly on the map. The District does not have an ambient monitoring location identified as WW_21. Monitoring station WW_21 should be identified as WW_24 and is located at the point on the map where WW_109 is indicated. Monitoring station WW_24 is located where WW_21 is indicated.

Response

Illinois EPA used latitude and longitude information from the MWRDGC website. If these are incorrect, new location information needs to be obtained. Illinois EPA received data from MWRDGC with monitoring data for station WW_21 (Salt Creek at First Avenue) from January 2001 until April 2002. WW-24 (Salt Creek at Wolf Road) has data from January 2001 until May 2007. WW_109 (Salt at Brookfield Road) has data from July 2002 until May 2007.

22. TMDL segments need to be better defined. It is practically impossible to determine from the maps where the segments begin and end. Segments should be defined by geographical features or, preferably, latitude and longitude coordinates.

Response

Illinois EPA will be more specific in the final stage 1 draft report. Individual maps of each impaired segment will be included along with a table that includes latitude and longitude coordinates for each monitoring station.

23. Despite the fact that the Illinois EPA identified the West Branch DuPage River as impaired due to zinc concentrations, no TMDL will be developed for this pollutant. The text of the report does not discuss the issue of zinc impairment of the West Branch DuPage River. This issue is only addressed as a footnote to Table 1-1. Based upon the identification of zinc impairment, the Illinois EPA has begun to place zinc limits in NPDES permits for municipal plants discharging to this river including the Village of Hanover Park Sewage Treatment Plant. Without conducting the formal TMDL process for zinc, there can be no assurance that the Illinois EPA's strategy will eliminate zinc impairment of the West Branch DuPage River. After extensive sampling and investigation of zinc concentrations within the Hanover Park sewer service area, it has been determined that the domestic concentrations of zinc are nearly the same as the industrial discharge concentrations. The domestic sewage accounts for roughly 80% of the WWTP flow while industry discharge only accounts for 20%. Even if industry is limited to zero discharge of zinc, the effluent would not meet the monthly zinc effluent limit of 0.046 mg/L. The technology to remove zinc and the cost associated with such an upgrade are significant. There is a concern that scarce tax dollars will be spent on point source control of zinc without solving the impairment.

Response

Domestic and industrial discharges are both considered point sources. The NPDES program has been established for control of point source discharges. This program is relied upon for reductions if there are impairments only due to point sources.

24. There is a single exceedance of manganese for segment GBK-14. That exceedance occurs during a period of relatively high sampling (4 year period accounting for perhaps 30 of the sample points). It would be of interest to know what the flow rates were when the outlier was sampled and see what proportion of the samples were collected under similar flow regimes. With one exceedance, the parameter does not meet the guideline for an impairment set out in the 2008 Integrated Assessment Report. In addition, it is our information that the standard for manganese is being revised for the State of

Illinois. In our assessment with the new standard, there is no exceedance. The TMDL for this parameter should be suspended.

Response

According to our assessment methodology (2008 Integrated Report on page 59, Table C-3) for aquatic life designated use, a single exceedance violates the chronic toxic standard for manganese. Once this standard is violated, the water body is impaired. Illinois EPA is in the process of developing new manganese standards, but this is in the initial stages. The Illinois Pollution Control Board must review and approve any changes to water quality standards before they can be utilized in Illinois EPA water quality assessments. In regards to flow analysis, as part of the stage 3 development a load duration curve will be utilized and this takes into account flow at the time each sample was taken. This can determine the flow regime in which violations take place and sources that attribute at that flow regime.

25. The two exceedences for chloride do not meet the standards set out in the 2008 Integrated Report for an impairment. However, there is DRSCW data that shows multiple exceedences for multiple sites and violations were correlated to storms. In addition, the Bioassessment plan found TDS higher than 1000 mg/L in several tributaries during summer months; chloride is most likely the bulk of these dissolved ions. We are satisfied that chloride levels are exceeded across the program area during winter months but also in a more limited area, warm weather periods, and that the principle source is winter de-icing compounds. Since you had poor data and there are de-icing operation already underway in the upper DuPage and Salt, a TMDL should not be completed for chloride. It is unlikely that such a development will contain more detailed analysis or recommendations than the 2007 DRSCW Chloride Usage Education and Reduction Study which was a completed due to the chloride TMDL allocations on the West and East Branches of DuPage.

Response

Please refer to the response for comment 14. Chloride is also a toxic chemical and falls under the same assessment as manganese. As required by the Clean Water Act, Illinois EPA will develop a TMDL. As with manganese, load duration curves will be utilized for chloride. Illinois EPA will have information in the implementation plan on the de-icing program/ chloride reduction study.

26. The silver data presented do not meet the standard set out in the Integrated Report. The Bioassessment study looked at 19 sites of the West Branch DuPage and all sites exceeded threshold levels, but did not exceed the probably effects levels as did PCBs found in sediment. Silver may be a problem, but not a priority at this time.

Response

Please refer to the response for comment 14. Silver is also a toxic chemical and falls under the same assessment protocol as manganese. Illinois EPA will not be developing a TMDL for PCBs in sediment as there are no standards for this parameter in sediment.

27. While agriculture may be an important source of nutrient loading, in terms of the Upper DuPage and Salt Creek the small proportion of the area with agriculture use means its effect should not be exaggerated. A more important source of nutrient loading is residential landscaping areas that are the dominant land use management practice in the areas and may produce up to 41% of the NPS phosphorus loadings in tributary watersheds (loadings in tributary watersheds Upper DuPage River Watershed Plan Update). This land use is ignored in chapter 5.3.

Response

While the Salt Creek watershed has only twelve percent agriculture land use, the DuPage River as over twenty percent. Residential areas are not ignored in the analysis. Urban Low/Medium Density which

represents residential areas comprise 30 percent in the DuPage River watershed and almost 47 percent in Salt Creek watershed.

28. Non-point source impairments are strong concerns for the ultimate health of the watershed. Wastewater plants in the region have already reached the point of cost effective treatment for these parameters. Significant investment in wastewater treatment will produce minimal benefit to the watershed. If additional improvements are required at wastewater plants, their carbon footprints are likely to increase thereby adversely affecting the quality of air in the region. We would highly encourage focusing on non-point sources.

Response

The TMDL will focus on all sources of pollutants and Illinois EPA is required to have allocations for both point and non-point sources in the watershed.

29. There has been substantial modification of the cross section of the West Branch of the DuPage River over the last few years, and additional modifications are anticipated over the next two or three years. During construction, the entire river flow is pumped around the construction site. It is well documented that when the water is inside pipes, organics remove DO from the water. This means that lower than normal DO levels should be occurring in the River whenever bypass pumping is being conducted on the River. In addition, a multi-year thorium removal project is expected to require two or three more years to complete. As a result, DO sampling of the river during this period will not be representative of the River's natural DO level after the work has been completed. IN addition, the dam in McDowell Woods Forest Preserve was removed in fall of 2008, and the dam in Warrenville is scheduled for removal in 2009. Removal of the dams is expected to increase DO levels in the previously impounded sections as well as downstream.

Response:

Regular monitoring of these waterways will continue and this includes DO. Assessment of the results should help focus the need and nature of any BMPs needed.

30. Based on a recent study on Salt Creek, significant phosphorus reductions in the Egan Plant's effluent did not have a measurable impact on either the algae biomass or DO. Egan supplies approximately 50% of the effluent received by Salt Creek. Studies have found a very strong correlation between habitat and diversity in fish and macro-invertebrate populations, suggesting that, at this time, habitat is the primary limiter in our streams and rivers. Therefore, we believe that a focus on habitat, rather than phosphorus removal, would be the most cost effective approach for improving aquatic life in local waterways.

Response:

As we are only in the water characterization stage, Illinois EPA has not done a source analysis. The stage 3 modeling will look at the permitted facilities and see if reductions need to be made by nonpoint and/or point sources. The TMDL Implementation Plan will be utilizing the biological study that was developed for this watershed and habitat improvement BMPs (best management practices) will be discussed.

31. Copper was identified as a municipal point source impairment for Spring Brook. We must ask that this be removed. Effluent sampling from the municipal point source that discharges to it does not show impairment. Please note that the January 4, 2006 data point was off by a factor of 10. That datum should have been recorded as 0.011 mg/L instead of 0.11 mg/L.

Response:

The municipal point source provided data for this assessment and the correction was made for the sampling data for January 4, 2006. According to these data, there was a sample from July 6, 2005 that

exceeded the chronic standard of 0.020 mg/L. According to our copper standard, this exceedance indicates moderate impairment in the stream.

32. Does the regular dissolved oxygen standard apply to all waters or does the enhanced protection standard apply to some of the waters in this watershed?

Response:

Language has been added to the report on waters with enhanced dissolved oxygen protection. Basically DuPage River segments GB-11, GB-16 and West Branch DuPage River segment GBK-02 are waters with enhanced protection for dissolved oxygen. These waters were assessed using the more stringent enhanced protection standard. Segment GB-16 is the only segment that is impaired for dissolved oxygen according to the enhanced protection standard.

Stage 3 Responsiveness Summary

DuPage River/Salt Creek Watershed Total Maximum Daily Load

The responsiveness summary responds to questions and comments received during the public comment period from April 24, 2019, through May 24, 2019.

What is a TMDL?

A Total Maximum Daily Load (TMDL) is the sum of the allowable amount of a pollutant that a water body can receive from all contributing sources and still meet water quality standards or designated uses. **The DuPage River\Salt Creek Watershed** TMDL report contains a plan detailing the actions necessary to reduce pollutant loads to the impaired water bodies and ensure compliance with applicable water quality standards. The Illinois EPA implements the TMDL program in accordance with Section 303(d) of the federal Clean Water Act and regulations thereunder.

Background

The watershed targeted for TMDL development is the **DuPage River\Salt Creek Watershed** located in northeastern Illinois and is approximately 520 mi2 (332,600 acres). The watershed includes the DuPage River (USGS HUC 0712000408) and Salt Creek (USGS HUC 0712000404) which are within Cook, Kendal, Will, Gundy, and DuPage counties. The DuPage River originates from two branches in the northern most part of the watershed. The West Branch DuPage River and East Branch DuPage River are approximately 35 miles and 25 miles long, respectively. Both branches flow south until they meet around Bolingbrook, creating the main branch of the DuPage River. The DuPage River approximately runs an additional 30 miles before the confluence with the Des Plaines River near the town of Channahon, IL. Spring Brook, another tributary to the DuPage River, flows southwest for approximately 5.5 miles before the confluence with the West Branch DuPage River.

Salt Creek and Addison Creek are 40 miles and 6.5 miles long, respectively, prior to their confluence approximately 3 miles upstream of the Des Plaines River. The Des Plaines River flows southwest, and after its confluence with the DuPage River, joins the Illinois River, a major tributary of the Mississippi River.

The Clean Water Act and USEPA regulations require that states develop TMDLs for waters on the Section 303(d) List. Illinois EPA has developed TMDLs for pollutants that have numeric water quality standards. Therefore, a Chloride TMDL was developed for DuPage River (IL_GB-11), a Fecal Coliform TMDL was developed for DuPage River (IL_GB-16), for West Branch DuPage River (IL_GBK-05, IL_GBK-09, and IL_GBK-14), for Spring Brook (IL_GBKA, and IL_GBKA-01), for East

Branch DuPage River (IL_GBL-10), for Salt Creek (IL_GL-09, IL_GL-10, and IL_GL-19), and for Addison Creek (IL_GLA-02).

These waterbodies are listed as impaired per the 2008 -2018 Draft Illinois Integrated Water Quality Reports and Section 303(d) List.

Illinois EPA contracted with TetraTech (a TMDL Consultant) to prepare the TMDL report for the DuPage River\Salt Creek Watershed project.

Public Meetings

A stage one public meeting was held in Elmhurst, IL on January 28, 2009. The Illinois EPA provided public notices for all meetings by placing an ad in the local newspapers in the watershed; the Chicago Daily Herald, The Will-South DuPage Report and the Central Cook Suburban. These notices gave the date, time, location, and purpose of the meetings. It also provided references to obtain additional information about this specific site, the TMDL Program and other related issues. Individuals and organizations were also sent the public notice by first class mail. An additional stakeholder meeting was held March 31, 2009 in Plainfield, IL. The draft TMDL Report was available for review at the Elmhurst City Hall and on the Agency's web page at: https://www2.illinois.gov/epa/topics/water-quality/watershed-management/tmdls/Pages/reports.aspx#dupsalt.

The draft Stage 3 public meeting was held on April 24, 2019, at 9:30 am, at the Village Hall in the Village of Lombard, IL. Approximately 63 people participated in the public meeting and the public comment period ended at midnight on May 24, 2019.

Illinois EPA provided public notice for all meetings by placing a display-ad in the Lombardian (the local newspaper in the Village of Lombard). In addition, a direct mailing was sent to DuPage River Salt Creek Workgroup (DRSCW), NPDES Permittees, and stakeholders in the watershed. The notice gave the date, time, location, and purpose of the meeting. The notice also provided references on how to obtain additional information about this specific project, the TMDL program, and other related information. The draft TMDL report was available for review in hard copy at The Conservation Foundation, DuPage County Stormwater Management, Village of Lombard, Village of Plainfield, and electronically on the Agency's webpage: www2.illinois.gov/epa/public-notices/Pages/general-notices.aspx.

Questions & Comments

 Page 35, Figure 15: The placement of the District's monitoring station WW_89 (Walnut Lane on West Branch DuPage River) is incorrect. WW_89 should be located in the upper part of river segment GBK-09. The GPS coordinates for WW_89 are N 41° 59' 45.02", W-88° 08' 10.87".

Response: Station WW_89 has been relocated as specified.

 Page 37, Figure 17: The placement of the District's monitoring station WW _18 (Devon Avenue on Salt Creek) is incorrect. WW_18 should be located in the lower part of river segment GL-10. The District's monitoring station WW_79 (Higgins Road on Salt Creek) is not depicted on the map figure. WW_79 is located in the lower part of river segment GL. The GPS coordinates for WW_18 are N 41 ° 59' 34.27", W -87° 59' 42.99". The GPS coordinates for WW _79 are N 42° 01' 53.70", W -88° 00' 40.40".

Response: Station WW_18 relocated as specified and station WW_79 added to Figure 17.

3. Page 38, Table 13: Segment GL-10 lists station WW_79, which is incorrect. WW _79 is actually in river segment GL. The summary statistics provided for segment GL-10 should be redone, excluding the data for station WW_79, in order to more accurately assess the FC impairment for that river segment.

Response: Fecal coliform data collected at station WW_79 removed from summary statistics as specified. WW_79 data also removed from the fecal coliform TMDL for GL-10 and the load duration curve (Figure 45) and TMDL summary tables (Table 55 and 56) have been updated; including the load reductions presented in Table 55 and Table 63.

4. Page 40, Figure 20: Time series data points are provided for river segments GL and GL-10. This figure should be double-checked to be sure that data from station WW_79 is not incorrectly being attributed to segment GL-10.

Response: Time series data points reviewed for segments GL and GL-10. No changes needed, data were collected at WW_79 beginning in 2008, which is not included on the figure in question.

5. Page 48, Section 5.3: The District's Westchester Pump Station is not listed or identified in Figure 31 as an existing NPDES permit discharge to Addison Creek.

Response: This discharge has been added throughout the document. Figures, tables and text in Section 5.3, Section 6.3.1, Section 7.11, Section 7.12 and Appendix E have been updated.

6. Page 155: The first paragraph makes an incorrect reference to the East Branch DuPage River in the first sentence and should actually be referencing the West Branch DuPage River.

Response: Text updated in report as noted.

Mr. Abel Haile Manager, Planning (TMDL) Unit Watershed Management Section, Bureau of Water Illinois Environmental Protection Agency 1021 North Grand Avenue East P.O. Box 19276 Springfield, IL 62794-9276

Dear Mr. Haile:

Subject: DuPage River/Salt Creek Watershed TMDL Draft Stage 3 Report

The Metropolitan Water Reclamation District of Greater Chicago (District) acknowledges receipt of the notification of TMDL Development and Potential NPDES Implications dated March 26, 2019. The District has reviewed the subject document and offers the following comments:

- Page 35, Figure 15: The placement of the District's monitoring station WW_89 (Walnut Lane on West Branch DuPage River) is incorrect. WW_89 should be located in the upper part of river segment GBK-09. The GPS coordinates for WW_89 are N 41° 59' 45.02", W -88° 08' 10.87".
- Page 37, Figure 17: The placement of the District's monitoring station WW_18 (Devon Avenue on Salt Creek) is incorrect. WW_18 should be located in the lower part of river segment GL-10. The District's monitoring station WW_79 (Higgins Road on Salt Creek) is not depicted on the map figure. WW_79 is located in the lower part of river segment GL. The GPS coordinates for WW_18 are N 41° 59' 34.27", W -87° 59' 42.99". The GPS coordinates for WW_79 are N 42° 01' 53.70", W -88° 00' 40.40".
- Page 38, Table 13: Segment GL-10 lists station WW_79, which is incorrect. WW_79 is actually in river segment GL. The summary statistics provided for segment GL-10 should be redone, excluding the data for station WW_79, in order to more accurately assess the FC impairment for that river segment.

BOARD OF COMMISSIONERS Kari K. Steele President Barbara J. McGowan Vice President Frank Avila Chairman of Finance Cameron Davis Kimberly Du Buclet Marcelino Garcia Josina Morita Debra Shore Mariyana T. Spyropoulos

- Page 40, Figure 20: Time series data points are provided for river segments GL and GL-10. This figure should be double-checked to be sure that data from station WW_79 is not incorrectly being attributed to segment GL-10.
- Page 48, Section 5.3: The District's Westchester Pump Station is not listed or identified in Figure 31 as an existing NPDES permit discharge to Addison Creek.

Pictured: DuPage River (Lower DuPage River Watershed Coalition)

1.0 INTRODUCTION

The DuPage River is located within the Chicago metropolitan area south of Naperville. The DuPage flows south to join the Des Plaines River which becomes the Illinois River at the confluence, flowing south to the Mississippi River. River segment GB-16 of the DuPage River is impaired for low dissolved oxygen (DO) concentrations, and extends approximately 10 miles (16 kilometers) downstream from the confluence of the East and West Branches of the DuPage River (Figure 1). The water quality standard for DO varies throughout the year, with a minimum concentration requirement of 5.0 mg/l from March to July, and 4.0 mg/l from August to February according to the Illinois Environmental Protection Agency.

QUAL2K is a one-dimensional steady-state river water quality model frequently used for simulating DO (Chapra et al., 2012). QUAL2K assumed a well-mixed stream channel (both vertically and laterally), and employs a diel, or 24-hour period, heat budget which can be used to model DO on an hourly basis. A QUAL2K model was developed and calibrated to DO data for the DuPage River segment GB-16 which was observed in early August, 2006. The model was setup and calibrated based on data availability for 8/1/2006. Model parameterization and assumptions were based on a combination of observed flow and water quality data as well as best professional judgement.

Figure 1. GB-16 of the DuPage River in the Chicago, Illinois area

2.0 QUAL2K MODEL SETUP

2.1 MODEL DATE SELECTION

The selection of the date on which to setup, run, and calibrate the DuPage River QUAL2K model was driven by data availability. Water quality grab samples have been conducted by Illinois EPA at sites GB-10, GB-10, WB35, and WB37 in the model vicinity. There is also USGS flow data available at sites 05540290, 05540275, 05540130, 05540250 which were used to parameterize the reach hydraulics. The key data that was used to identify the calibration date for the model was based on the only continuous dissolved oxygen sampling data available, which was at site GB-08 from 7/24/2006 – 8/2/2006 on 30-minute sampling intervals. Based on the data availability of continuous DO data, the model was setup and calibrated for 8/1/2006.

2.2 MODEL SEGMENTATION AND REACH INPUTS

The DuPage River segment of-interest was subdivided into four model reaches. All model reaches were assigned identical hydraulic properties due to a lack of field-specific data to suggest otherwise. The river was segmented at each major tributary inflow, and elevation data were assigned using a 3-meter digital elevation model (DEM) obtained from USDA Data Gateway. Each model reach is further broken down in the model elements. Table 1 and Figure 1 summarize the reach segmentation for GB-16.

Reach	Description	Reach Length (km)	Number of 0.1-km Elements	Upstream Elevation (m)	Downstream Elevation (m)
1	West and East Branch DuPage River confluence to Spring Brook	0.85	9	190.73	189.93
2	Spring Brook to Wolf Creek	5.35	54	189.93	185.37
3	Wolf Creek to Norman Ditch	5.78	58	185.37	181.71
4	Norman Ditch to GB-08 sample site	4.10	41	181.71	178.88

Table 1. Reach segmentation for GB-16 QUAL2K model

Stream hydraulics were simulated using the rating curve method within QUAL2K, and were identical for all model reaches. QUAL2K employs power equations to relate mean velocity (*U*) and depth (*H*) to flow for the elements in a reach: $U = aQ^b$ and $H = \propto Q^\beta$, such that *a*, *b*, \propto , and β are empirical coefficients determined from velocity-discharge and stage-discharge rating curves. USGS provides a rating curve for its gage 05540290 (DuPage River near Plainfield, Illinois) which is located along the DuPage River segment of-interest. The relationship between gage height, stream discharge, and USGS field measurements of depth and velocity at this location were used to determine the model inputs as follows: 0.2506 for *a*, 0.3449 for *b*, 0.1237 for \propto , and 0.4322 for β .

Inputs related to bottom algae coverage and prescribed reaeration rates drive diurnal DO cycling within the system, so those parameters were developed during the model calibration process (Table 2). Instream DO concentrations are very sensitive to sediment oxygen demand (SOD), for which the prescribed

bottom coverage percentage and rate work in tandem to approximate. SOD monitoring was conducted along the West Branch and mainstem DuPage River during the Illinois EPA Stage 2 TMDL process in 2009. SOD was measured by CDM at the DuPage River at Naperville 100 yards upstream of the WWTP discharge (as well as upstream locations along the West Branch) and the observed temperature-corrected SOD rate at this location was 5.58 g/m²/d. This observed SOD rate was used in the model for the entire segment, although the percent SOD coverage was estimated through the calibration process. SOD rates along the West Branch ranged from 2.04 to 4.88 g/m²/d. SOD rates have been reported from 0.56 to 8.08 g/m²/d in northeastern Illinois (Butts, 1974). The sediment diagenesis model computes SOD and nutrient fluxes in-stream in addition to the prescribed SOD rate and coverage observed under existing conditions.

The bottom algae coverage was estimated through the calibration process as well, but was based in part on anecdotal evidence from the 2012 Biological and Water Quality Study of the Lower DuPage River Watershed report conducted by the Midwest Biodiversity Institute. This bioassessment report for the DuPage River details the "lush macrophyte growth" along this section of the DuPage River, as well as "pooled or sluggish" nature of flow in this extent, which was used to inform the reaeration rate of 0.95 /d.

Parameter	Input
Prescribed Reaeration (/d)	0.95
Bottom Algae Coverage	90%
Bottom SOD Coverage	15%
Prescribed SOD (g/m ² /d)	5.58
Bottom Algae Max Growth Rate (/d)	1.30
Bottom Algae Respiration Rate (/d)	0.30
Bottom Algae Excretion Rate (/d)	0.001
Bottom Algae Death Rate (/d)	0.10
Bottom Algae Growth Model	First-order
Bottom Algae Carrying Capacity (mgA/m ²)	150

Table 2. Reach rate inputs

2.3 METEOROLOGICAL INPUTS

Metrological inputs to the QUAL2K model are air temperature, dew point temperature, wind, cloud cover, and shade. In order to represent generic summer conservative conditions, the GB-16 model was set up to assume clear skies (0% cloud cover for all reaches at all hours, also suggested by local meteorological data) and full sun (0% shade for all reaches at all hours, which is bolstered by an analysis of aerial imagery and local observation). Hourly inputs for air and dew point temperatures and wind speed were applied to all reaches based on observed data on 8/1/2006 at nearby West Chicago DuPage Airport (NOAA WBAN 94892). Average conditions that day were 30.3°C air temperature, 24.4°C dew point, and wind speed 11 mph.

2.4 HEADWATER INPUTS AND INITIAL CONDITIONS

The headwater reaches for this model are the West and East Branches of the DuPage River. Because there is not sufficient observed data to parameterize these headwater reaches uniquely, they were modeled as a single headwater inflow. Observed flow on 8/1/2006 at USGS gages on either branch (05540130 West Branch DuPage River near Naperville, IL and 05540250 East Branch DuPage River at Bolingbrook, IL) were combined for a single model input (Table 3). Water quality input parameters for the headwaters were based on limited observed water quality data at two sampling sites along the West Branch DuPage River (WB35 and WB37) which were sampled by the DuPage River Salt Creek Workgroup (DRWCW), as well as observations of water quality conditions immediately downstream of the confluence as measured by the 2012 bioassessment report, and conditions at water quality site GB-10. The East and West Branches of the DuPage River are described in the bioassessment report as being largely effluent-dominated streams, which is why nutrient levels such as nitrate are considerably high compared to streams which are not effluent-dominated. The bioassessment report found that, for example, effluent composed 76% of total flow in the East Branch DuPage River in September 2007.

Within the model, the downstream extent was not a prescribed boundary.

Parameter	Model Input
Flow Rate (m ³ /s)	1.926
Elevation (m)	191.00
Hydraulic Formula	Rating Curve
Water Temperature (°C)	29.0
Conductivity (µmhos)	936
Inorganic Solids (mgD/L)	8.6
Dissolved Oxygen (mg/L)	8.0
CBODslow (mgO ₂ /L)	1.0
CBODfast (mgO ₂ /L)	1.0
Organic Nitrogen (µgN/L)	600.0
NH4-Nitrogen (µgN/L)	95.0
NO3-Nitrogen (µgN/L	6000.0
Organic Phosphorus (µgP/L)	100.3
Inorganic Phosphorus (µgP/L)	1124.8
Alkalinity (mg/L)	232.0
Phytoplankton (mgA/L)	4.82
рН	8.15

Table 3. Headwater inputs

2.5 POINT SOURCE INPUTS

Point sources explicitly modeled includes three tributaries: Spring Brook, Wolf Creek, and Norman Ditch, as well three NPDES-permitted municipal wastewater treatment facilities which discharge directly into the modeled reach: Naperville Springbrook STP (IL0034061), Bolingbrook STP #3 (IL0069744), and Plainfield North STP (IL0074373) (Table 4). There are numerous other point sources located upstream of the impaired reach, but the combined impact of these other point sources was estimated based on the assumed headwater water quality conditions. Permitted point source water quality inputs were based on reported monthly averages for August 2006 based on discharge monitoring records (DMRs), and an assumed total phosphorus (TP) concentration of 4000 µg/L and phosphorus speciation (organic and inorganic phosphorus) based on municipal wastewater generalizations. These WWTPs currently have TP limits of 1000 µg/L which were not in place during 2006. Reported 5-day carbonaceous biochemical oxygen demand (CBOD₅) concentrations were multiplied by two which is considered the accepted relationship between measured CBOD₅ and QUAL2K "Fast CBOD_{ultimate}" concentration. For reference, the monitored monthly average CBOD₅ concentrations for Naperville, Bolingbrook, and Plainfield WWTPs were 1, 3, and 3.3 mg/L respectively, therefore the model inputs for fast CBOD_{ultimate} were 2, 6, and 6.6 mg/L for these constituents. The Illinois Environmental Protection Agency provides data from permitted point sources via the Discharge Monitoring Report (DMR) system, which are summarized in Table 5, Table 6, and Table 7.

Point source model inputs for tributaries were developed using limited observed data. Observed flows were available from the USGS gage 05540275 on Spring Brook, which were used to estimate area-weighted flows for both Wolf Creek and Norman Ditch. Water quality sampling was available from the same USGS gage on 8/2/2006 (day after the calibration date) for parameters such as water temperature, dissolved oxygen, and conductivity. Tributary nutrient concentrations were populated using a combination of Spring Brook USGS concentrations as well as available monitoring from the bioassessment report. There were no diffuse sources included in the QUAL2K model.

Parameter	Spring Brook	Wolf Creek	Norman Ditch	IL0034061 (Naperville STP)	IL0069744 (Bolingbrook STP #3)	IL0074373 (Plainfield North STP)
Location (km)	15.25	9.89	4.10	14.51	8.39	2.93
Inflow (m ³ /s)	0.0907	0.0438	0.0591	0.8706	0.0784	0.1257
Water Temperature (°C)	29.0	29.0	29.0	29.0	29.0	29.0
Specific Conductance (µmhos)	950	850	850	n/a	n/a	n/a
Dissolved Oxygen (mg/L)	9.1	9.1	9.1	6.1	6.1	6.1

3.0 QUAL2K MODEL RESULTS

Based on the model setup detailed above, the QUAL2K model was built for the Lower DuPage River segment GB-16. The model was calibrated to DO concentrations measured every half-hour at the downstream end of the segment (site GB-08 in Figure 1; Model Element 41 of Reach 4) on the calibration date of 8/1/2006. Key calibration parameters included parameters for which the assumed initial conditions and rates had the most uncertainty. For example, there was little data to inform the water temperature within the model, as well as bottom algae and SOD percent coverages. Some of these parameters will be discussed further in sensitivity analysis results in Section 4.0.

3.1 MODEL RESULTS

A reasonable fit between the observed DO data and the QUAL2K simulated DO concentrations was achieved based on the aforementioned setup. The observed DO minimum, maximum, average, and median were achieved in the model results quite well, which suggests that the model adequately approximates the system based on the available data (Table 8, Figure 2). The DO results are compared to the water quality standard of 4.0 mg/l which applies from August – February.

The relative locations of point source inputs can be seen along the longitudinal plot of DO concentrations modeled along the full extent (Figure 3). DO concentrations dip on a scale relative to flow at the input of each point source due to increased nutrient concentrations and decreased DO concentrations. In general there is a slight increase in DO occurring along the reach length due to the presence and growth of bottom algae within the stream. The wide range of minimum and maximum DO concentrations seen in Figure 3 are indicative of the observed diel swing in DO concentrations over the course of 24 hours, as depicted in Figure 2.

Statistic	Observed DO	Modeled DO	Percent Error
Minimum	3.86	3.86	-0.11%
Maximum	13.70	13.61	-0.67%
Average	8.37	8.23	-1.64%
Median	7.83	7.82	-0.12%

Table 8. Model and observed dissolved oxygen concentrations, Reach 4 Element 41

Figure 2. Observed and modeled diel dissolved oxygen concentration results, Reach 4 Element 41

Figure 3. Modeled average, minimum, and maximum dissolved oxygen concentrations along the entire model extent

4.0 MODEL SENSITIVITY AND SCENARIOS

4.1 MODEL SENSITIVITY

A number of sensitivity analyses were conducted to see how to model would respond to changes in certain initial conditions, rates, and inputs. Sensitivity analyses included the following, as well as their relative impact on the calibrated diel DO at reach 4, element 41 (Table 9, Figure 4). Diel DO cycling is most impacted by bottom algae and sediment oxygen demand parameters based on this sensitivity analysis.

Table 9. Sensitivity analyses descriptions and results

Run	Sensitivity Run Description	Impact
1	Decrease headwater total phosphorus to zero	Small decrease in average, minimum, and maximum DO (min DO 3.82 mg/L) due to less in-stream photosynthesis in response to less in-stream nutrient availability.
2	Decrease headwater temperature by 2 degrees C	Small decrease in average and maximum DO, small increase in DO minimum (min DO 3.96 mg/L). The decline in average DO and paired increase/decrease in min/max DO is due to the lower temperature resulting in slightly less bottom algae proliferation in the system which impacts the diurnal range of DO.
3	Increase headwater DO by 2 mg/L	Increase in average, maximum, and minimum DO (min DO 4.39 mg/L).
4	SOD coverage doubled to 30%	Large decrease in average, maximum, and minimum DO (min DO 2.35 mg/L).
5	SOD rate decreased by half	Large increase in average, maximum, and minimum DO (min DO 4.62 mg/L).
6	Decrease bottom algae coverage by half	Increase in minimum DO, and large decrease in average and maximum DO due to a decrease in diel amplitude (min DO 4.85 mg/L). When algae is removed from the system there is a dampening of the diurnal DO fluctuation so both maximum and minimum DO are closer to the mean, which also decreases due to the decrease in in-stream photosynthesis.

Figure 4. Model sensitivity of diel DO to various parameter changes

4.2 MODEL SCENARIOS

Various model scenarios (Table 11) were considered in order to estimate the impact of critical conditions along the Lower DuPage River (GB-16) in regards to stream conditions and point source discharges. By creating a condition at which point sources are discharging their respective allowable effluent flows and concentrations, scenarios will be used to estimate in-stream DO compared to the DO standard. For these scenarios, an explicit margin of safety was added by increasing the minimum DO concentration by 10%, resulting in a minimum DO concentration target of 4.4 mg/L.

Under the calibrated model conditions, the observed minimum DO on 8/1/2006 was 3.86 mg/L, which is below the water quality standard of 4.0 mg/L. A critical condition scenario was developed for which the three permitted point sources were modeled at their monthly average permit limits (Table 10). Under these conditions, headwater flows were decreased to the seven-day ten-year (7Q10) low flow condition of 1.699 cms (Illinois State Water Survey, 2003), while flows at the three point sources were increased to 1.31 cms, 0.18 cms, and 0.33 cms, respectively for Naperville STP, Bolingbrook STP, and Plainfield STP (Table 10). Under existing conditions, minimum DO concentrations were below 4.0 mg/L; increasing WWTP effluent flows and nutrient concentrations to permit limits exacerbated the condition, resulting in a large decrease in DO throughout the system (Scenario 1).

Parameter	Naperville WWTP (IL0034061)	Bolingbrook WWTP (IL0069744)	Plainfield WWTP (IL0074373)
Design Average Flow, cms (MGD)	1.31 (30.0)	0.18 (4.2)	0.33 (7.5)
Suspended solids (mg/L)	12	25	25
CBOD₅ (mg/L) ¹	10	20	20
Ammonia (µg/L)	1400	1500	1500
Total Phosphorus (mg/L) ²	1	1	1
DO (mg/L)	6.0	6.0	6.0

Table 10. NPDES point source permit monthly average concentration limits

¹These values are the existing permit limits; recall, as detailed in Section 2.5, that a concentration of CBOD₅ is multiplied by two for the model input of fast CBOD_{ultimate} as per model input requirements.

²Original permits allowed maximum discharge of 4.0 mg/L TP, but the facilities are currently being updated to account for a new 1.0 mg/L TP effluent limit. TP concentration is split for model input as and assumed 72.3% dissolved phosphorus, and 27.7% organic phosphorus.

Scenario 2 and 3 include the same permitted conditions as Scenario 1, although certain modifications were made to meet the water quality standard with the margin of safety. Both Scenarios 2 and 3 include decreasing in-stream prescribed SOD to 2.04 g/m²/d which was the lowest observed SOD along the West Branch DuPage River, increased point source DO to 6.5 mg/L which can be attained through aeration, headwater TP decreased to 1 mg/L, and decreased Bolingbrook and Plainfield CBOD₅ concentrations to the same limit as Naperville WWTP (inputs detailed in Table 11). The key differences between Scenarios 2 and 3 are the ways in which the WQS is achieved, either by decreasing the Naperville WWTP CBOD₅ to 7.5 mg/L with an in-stream SOD coverage of 7.5% (Scenario 2), or by maintaining existing CBOD₅ limits and decreasing SOD coverage to 5% (Scenario 3). The results of these scenarios as compared to the calibrated model are seen in Figure 5.

Table 11. Model scenarios

Scenario	Scenario Description
1	 Critical conditions: Headwater flow decreased to 1.699 cms Headwater DO decreased to 6 mg/L Point source flows and water quality changed to details in Table 10
2	 Scenario 1 with the following modifications to meet WQS with MOS: SOD rate reduced to 2.04 g/m²/d Point source minimum DO increased to 6.5 mg/L Bolingbrook and Plainfield WWTPs CBOD₅ decreased to 10 mg/L Headwater TP decreased to 1 mg/L Naperville WWTP CBOD₅ decreased to 7.5 mg/L SOD coverage decreased by half to 7.5%
3	 Scenario 1 with the following modifications to meet WQS with MOS: SOD rate to 2.04 g/m²/d Point Source DO minimum increased to 6.5 mg/L Bolingbrook and Plainfield WWTPs CBOD₅ decreased to 10 mg/L

Scenario	Scenario Description
	 Headwater TP decreased to 1 mg/L Naperville WWTP CBOD₅ unchanged SOD coverage decreased to 5.0%

Figure 5. Model scenarios diel DO compared to observed data and calibrated model

In the calibrated model, SOD is prescribed at a baseline of 5.58 g/m²/d due to upstream conditions (this rate has been observed). In Scenario 1, the in-stream SOD increases dramatically longitudinally due to the point source inputs to a downstream average condition of approximately 9.35 g/m²/d. The average instream SOD downstream of point source influence in Scenarios 2 and 3 are 4.60 and 5.62 g/m²/d respectively due to differing in-stream prescribed SOD conditions and effluent characteristics.

4.3 TMDL ALLOCATIONS

Two TMDL scenarios (Scenario 2 and 3) are used to demonstrate allocations that meet the loading capacity in the stream based on critical conditions during which the DO standard is met with a 10% margin of safety (Table 12). Point source reductions are needed to meet the minimum DO concentration. Since there are different pollutant combinations that can result in the same in-stream DO condition, point source facilities can consider the different options as part of TMDL implementation.

An example load calculation from Scenario 2 of Total Phosphorus for the Naperville STP point source is provided below:

 $Load = Flow \times Concentration$

Naperville STP flow: 1.31 cms

Naperville STP total phosphorus: 1.0 mg/l

 $\begin{aligned} \text{Naperville STP TP Load} &= 1.31 \frac{m^3}{s} \times 1.0 \ \frac{mg}{L} \times \text{unit conversion} \ \Big(\frac{86400 \ s}{d} \times \frac{1000 \ L}{m^3} \times \frac{1 \ lb}{453592 \ mg} \Big) \\ \text{Naperville STP TP Load (Scenario 2)} &= 250 \ \frac{lbs}{d} \end{aligned}$

Table 12. TMDL load and wasteload allocations (Sce	enarios 2 and 3)
--	------------------

Leasting	Total Phosphorus	Total Ammonia	CBOD ₅ Load

Pictured: West Branch DuPage River at Springinsguth Road (DuPage River/Salt Creek Work Group)

1.0 INTRODUCTION

The West Branch DuPage River originates in the Village of Schaumburg and flows south to join the DuPage River and eventually the Illinois River. The West Branch DuPage River reach of-interest is a headwater reach (GBK-14) which flows from approximately West Schaumburg Road down to the Hanover Park Wastewater Treatment Plant. River segment GBK-14 is 3.83 miles (6.16 kilometers) long, and is impaired for low dissolved oxygen (DO) concentrations (Figure 1). There are limited data available in the area related to water sources, flow, and water quality. The DuPage River Salt Creek Workgroup collected additional data in 2016 to support this modeling effort. The Illinois EPA's water quality standard for DO for this reach varies throughout the year, with a minimum concentration requirement of 5.0 mg/l from March to July and a 4.0 mg/l from August to February. GBK-14 was modeled in an effort to simulate existing instream conditions, identify potential causes of impairment, and run scenarios under which water quality standards may be met.

QUAL2K is a one-dimensional steady-state river water quality model frequently used for simulating DO (Chapra et al., 2012). QUAL2K assumes a well-mixed stream channel (both vertically and laterally), and employs a diel, or 24-hour period, heat budget which can be used to model DO on an hourly basis. A QUAL2K model was developed and calibrated for the GBK-14 for based on data availability for 9/3/2016. Model parameterization and assumptions were based on a combination of observed flow and water quality data as well as best professional judgement.

Figure 1. West Branch DuPage (GBK-14) in Cook County, Illinois

2.0 SUMMARY OF AVAILABLE DATA

There are three sources of available water flow and water quality data associated with reach GBK-14:

- Sediment oxygen demand (SOD) sampling conducted by CDM upstream of the Hanover Park WWTP during the Illinois EPA Stage 2 TMDL process in 2009. Observations at this site found channel bed sediments had an SOD of 1.96-2.11 g/m²/d, with an average of 2.04 g/m²/d (CDM, 2009).
- 2. The DuPage River Salt Creek Workgroup (DRWCW) conducted a sampling effort in September 2016 including the following items at the crossing of Springinsguth Road: channel cross-sectional surveys, velocity measurements, and algae surveys on 9/2/2016 and 9/6/2016, water quality samples on 9/2/2016, 9/6/2016, and 9/7/2016 which were analyzed for a suite of parameters including: DO, CBOD, pH, alkalinity, nutrients, chlorophyll a, and dissolved solids. A continuously-recording data sonde was deployed at the Springinsguth Road location as well that recorded specific conductivity, DO, pH, and water temperature at hourly increments from 9/1/2016 to 9/7/2016.
- The Metropolitan Water Reclamation District of Greater Chicago (MWRD) collected a single water quality sample on 9/6/2016 at the Springinsguth Road sampling site that was analyzed for a suite of water quality parameters including: DO, CBOD, temperature, pH, alkalinity, nutrients, chlorophyll a, fecal coliform, and a variety of metals, salts, and solids.

These data observations from September 2016 will be used to parameterize and calibrate the QUAL2K model for GBK-14 and are summarized in Appendix A.

3.0 QUAL2K MODEL SETUP

3.1 MODEL SEGMENTATION AND REACH INPUTS

In the QUAL2K model, a river may be segmented into different reaches if those reaches are anticipated to have differences from one another in regards to reach hydraulic properties, atmospheric inputs, or stream shading. While there are some visually apparent variability along GBK-14 in regards to stream shading and channel width, without any calibration data to inform the impacts of these differences on the channel, a single model reach may be used to approximate the average conditions of the entire reach. For this reason, the West Branch DuPage River segment GBK-14 was modeled as a single reach... The modeled river segment flows from headwaters at W Schaumburg Road down to the entrance of the box culvert north of Irving Park Road. Reach GBK-14 was truncated in the modeling environment at the box culvert entrance because there is not flow or water quality data downstream of that point to inform model development and calibration. It may be possible that the box culvert serves to reaerate the stream due to a change in channel geometry while the stream flows underground at this point, but without data the impacts cannot be known. The model reach was assigned hydraulic properties developed from the single Springinsguth Road survey site and adjusted during calibration to capture the reach characteristics. Elevation data were assigned using a 1-meter LiDAR-derived digital elevation model (DEM) obtained from the Illinois Height Modernization Program. The model reach was segmented into 52 internal 0.1-

kilometer computational elements. Table 1 and Figure 1 summarize the reach segmentation and hydraulic properties for GBK-14.

Model Input	Reach 1
Description	GBK-14 headwaters from W
	Schaumburg Road to the entrance of
	the box culvert
Reach Length (km)	5.15
Count of 0.1-km Elements	52
Upstream Elevation (m)	243.34
Downstream Elevation (m)	238.64
Hydraulic Model	Manning Formula
Channel Slope	0.0001
Manning's "n"	0.065
Bottom Width (m)	6.50
Water Depth (m)	0.14
Side Slopes	0 (assumed rectangular channel)

Table 1. Reach hydraulic properties for GBK-	-14 QUAL2K model
--	------------------

Stream hydraulics were simulated using the Manning Formula. QUAL2K approximates stream flow using the following input parameters for this hydraulic model: channel slope, Manning's "n", bottom width, and channel side slopes. Observations of water depth, velocity, and discharge were taken on 9/2/2016 and 9/6/2016 which were used as bounding data for calibration of reach hydrology. Model inputs for slope, bottom width, and Manning's n were approximated based on the channel surveys, and calibrated to observed hydraulics. Note that a Manning's n of 0.065 reflects slow-moving, very low flow conditions. Low flow conditions are most easily highlighted by the observed average water depths on 9/2/2016 and 9/6/2016 which were 0.51 and 0.21 feet deep (0.16 and 0.06 meters) respectively.

Inputs related to bottom algae coverage and prescribed reaeration rates drive diurnal DO cycling within the system, so those parameters were developed during the model calibration process and bolstered by in-stream water quality sampling and algae observations (Table 2). In-stream DO concentrations are very sensitive to sediment oxygen demand (SOD), for which the prescribed bottom coverage percentage and rate work in tandem to approximate. The observed SOD rate of 2.04 g/m²/d from the 2009 CDM sampling was used in the model, with a bottom coverage rate determined through calibration to be 44%. The sediment diagenesis model computes SOD and nutrient fluxes in-stream in addition to the prescribed SOD rate and coverage observed under existing conditions. For reference, SOD rates have been reported from 0.56 to 8.08 g/m²/d in northeastern Illinois (Butts, 1974). High SOD values are typically related to effluent-dominated streams in the DuPage area. Because there are no upstream WWTPs discharging to GBK-14, carbonaceous biochemical oxygen demand (CBOD) present in the stream is likely to be "slow CBOD" or refractory, slow-decaying CBOD raster than the labile effluent-associate "fast CBOD".

Note that most other reach rate inputs were estimated and identified based on in-stream calibration efforts (Table 2). All in-stream parameterization related to sediment and nutrient fluxes were modeled conservatively since there is no available information on decay and settling rates along GBK-14. Phytoplankton parameters were held at model defaults.

Parameter	Input	Note
Prescribed Reaeration (/d)	1.1	Developed during calibration in tandem with SOD coverage to meet observed average DO at Springinsguth Road
Bottom Algae Coverage	50%	Developed during calibration
Bottom SOD Coverage	46%	Developed during calibration in tandem with prescribed reaeration coverage to meet observed average DO at Springinsguth Road
Prescribed SOD (g/m ² /d)	2.04	Observed
Slow CBOD Oxidation Rate (/d)	0.04	Developed during calibration
Fast CBOD Oxidation Rate (/d)	0.00	Fast CBOD is associated with effluent discharge; there is no fast CBOD assumed present
Bottom Algae Max Growth Rate (/d)	9.0	Developed during model calibration
Bottom Algae Respiration Rate (/d)	1.0	largely to capture the observed diurnal range in DO concentration due to in-
Bottom Algae Excretion Rate (/d)	0.1	stream photosynthesis and respiration
Bottom Algae Death Rate (/d)	0.1	1
Bottom Algae Growth Model	Zero-order	1

3.2 LIGHT AND HEAT RATES

For the most part, light and heat parameters were held at model default values. The solar shortwave radiation model chosen was the Ryan-Stolzenbach, with an atmospheric transmission coefficient of 0.70. The atmospheric longwave emissivity model chosen was the Brutsaert model which can be appropriate for calculating air emissivity in warm conditions. Through calibration, the wind speed function for evaporation and air convection/conduction was chosen to be Adams 1 which is used to estimate the impact of wind on air and water temperatures. Some sediment thermal heat properties (sediment thermal diffusivity, sediment density, sediment heat capacity) were increased in order to attain water temperature calibration based on naturally occurring sediment conditions (Lapham, 1989).

3.3 METEOROLOGICAL INPUTS

Metrological inputs to the QUAL2K model are air temperature, dew point temperature, wind, cloud cover, and shade (Table 3). Hourly air and dew point temperatures were obtained for the calibration date of 9/3/2016 from the Chicago O'Hare International Airport (NOAA WBAN 94846). Hourly wind speed was estimated as zero to be conservative for dry, summer, stagnant conditions. Hourly cloud cover has an impact on the range (minimum and maximum) water temperatures attain throughout the day. The cloud cover was estimated at 75% during calibration in order to achieve the relative low diurnal variation in observed water temperatures. The average effective shade has a large impact on stream temperature as well, and the estimated shade for the entire model reach was 60%.

Hour	Air Temperature (°C)	Dew Point Temperature (°C)
12:00 AM	18.9	14.4
1:00 AM	18.9	13.9
2:00 AM	17.8	13.9
3:00 AM	16.1	12.8
4:00 AM	15.0	12.8
5:00 AM	14.4	12.8
6:00 AM	15.0	12.8
7:00 AM	17.8	13.3
8:00 AM	19.4	13.3
9:00 AM	21.1	13.9
10:00 AM	22.2	13.9
11:00 AM	23.3	12.2
12:00 PM	23.9	12.8
1:00 PM	23.9	11.7
2:00 PM	23.9	11.7
3:00 PM	24.4	11.7

9:00 PM	19.4	14.4

Table 3. Hourly variable meteorological inputs for model date 9/3/2016

Hour	Air Temperature (°C)	Dew Point Temperature (°C)
10:00 PM	18.9	15.0
11:00 PM	17.8	15.0

3.4 HEADWATER INPUTS AND INITIAL CONDITIONS

Water quality samples from the Springinsguth Road site were used to parameterize and calibrate the model. The headwaters of GBK-14 are represented with median observed water quality for nearly all parameters (Table 4). Within the model, the downstream extent was not a prescribed boundary, and there were no diffuse or point sources included in this model.

Table 4. Headwater inputs for GBK-14 QUAL2K model

Parameter	Model Input	Note
Flow Rate (m ³ /s)	0.038	Flow was estimated on 9/2/2016 as 0.047 m ³ /s and on 9/6/2016 as 0.012 m ³ /s at the sampling site. Linear interpolation between these two dates was used to estimate flow on 9/3/2016 as 0.038 m ³ /s.
Elevation (m)	243.35	Estimated from LiDAR data
Hydraulic Model	Manning Formula	Inputs same as Reach 1
Water Temperature (°C)	19.4	Average observed water temperature at 9/3/2016 at the sampling site.
Conductivity (µmhos)	1062.5	Average observed conductivity at 9/3/2016 at the sampling site.
Inorganic Solids (mgD/L)	3.0	Median of observed data on 9/2, 9/6, and 9/7.
Dissolved Oxygen (mg/L)	5.5	Headwater DO conditions are unknown, so they have been conservatively set to the summer water quality standard of 5.0 mg/L with an added 10% margin of safety.
CBODslow (mgO ₂ /L)	2.5	Median of observed data on 9/2, 9/6, and 9/7 is 2.40 mg/L. There is likely CBOD oxidation occurring in-stream, so headwater conditions were estimated slightly higher.
CBODfast (mgO ₂ /L)	0.0	Assumed zero.
Organic Nitrogen (µgN/L)	2580.0	Median of observed data on 9/2, 9/6, and 9/7.
NH4-Nitrogen (µgN/L)	50.0	Median of observed data on 9/2, 9/6, and 9/7.
NO3-Nitrogen (µgN/L	360.0	Median of observed data on 9/2, 9/6, and 9/7.

Parameter	Model Input	Note
Organic Phosphorus (µgP/L)	30.0	Median of observed data on 9/2, 9/6, and 9/7.
Inorganic Phosphorus (µgP/L)	610.0	Median of observed data on 9/2, 9/6, and 9/7.
Phytoplankton (µgA/L)	1.6	Median of observed data on 9/2, 9/6, and 9/7.
Alkalinity (mg/L)	214.5	Median of observed data on 9/2, 9/6, and 9/7.
рН	7.2	Median of observed data on 9/2, 9/6, and 9/7.

4.0 QUAL2K MODEL RESULTS

Based on the model setup detailed above, the model was calibrated to DO concentrations and water temperature measured every hour at the location of the sampling site at Springinsguth Road on the calibration date of 9/3/2016. This sampling site corresponds with model reach element 37. Various other water quality parameters such as nutrients were considered to be conservative in the system (no gains or losses) because there were no upstream or downstream measurements relative to the Springinsguth Road sampling site to inform decay rates or in-stream processes. This conservative assumption is reasonable because the nutrient concentrations observed were quite small and do not appear to have a significant impact on the system. Observed hourly water temperature, DO, conductivity, and pH data used for calibration on 9/3/2016 for element 37 are detailed in Table 5.

Hour	Water Temp (°C)	DO (mg/L)	Conductivity (umhos)	рН
12:00 AM	19.71	3.65	1041	7.21
1:00 AM	19.45	3.64	1044	7.21
2:00 AM	19.23	3.71	1047	7.2
3:00 AM	19.01	3.70	1050	7.19
4:00 AM	18.81	3.70	1053	7.18
5:00 AM	18.61	3.77	1057	7.18
6:00 AM	18.4	3.74	1061	7.17
7:00 AM	18.22	3.77	1060	7.16
8:00 AM	18.04	3.78	1055	7.16
9:00 AM	18.03	3.81	1054	7.16
10:00 AM	18.18	3.86	1052	7.17
11:00 AM	18.51	3.91	1053	7.19

11:00 PM	20.05	3.55	1066	7.21

4.1 MODEL RESULTS

A reasonable fit between the observed DO data and the QUAL2K simulated DO concentrations was achieved based on the aforementioned setup. The observed DO minimum, maximum, average, and median were achieved in the model results quite well, which suggests that the model adequately approximates the system based on the available data (Table 6, Figure 2). There is also a good fit between modeled and observed water temperature. By approximating the observed range of minimum and maximum water temperature and DO suggests that the model inputs associated with weather conditions and in-stream chemistry are reasonably simulated at the calibration point.

The modeled longitudinal changes in dissolved oxygen as compared with observed data are depicted in Figure 3. In general there is a decrease in DO occurring along the reach length which may be due to a number of factors such as low reaeration, high SOD, low channel gradient, low flow volume, or unknown variables such as unknown discharges. There is a large amount of uncertainty associated with the upstream and downstream ends of the simulated portion of GBK-14 due to lack of data. Note that if headwater DO is significantly higher or lower than the assumed concentration of 5.5 mg/l, then in-stream DO sources and demands may not be simulated properly relative to the existing conditions.

Model calibration was achieved based on prioritization of measured hydraulics, diel water temperature, and diel DO data. Observed hydraulic data used for hydrology calibration were velocity measurements of 0.036 and 0.063 m/s, and average depth measurements of 0.064 and 0.155 meters. These measurements serve to bracket to model flows appropriately, for which modeled velocity was 0.04 m/s, and stream depth was 0.14 meters.

Table 6. Simulated and observed DO (mg/L) and water temperature (°C), model element 37, calibrated model

Statistic	Observed DO	Modeled DO	Percent Error in DO	Observed Water Temperature	Modeled Water Temperature	Percent Error in Temperature
Minimum	3.6	3.7	4.6%	18.0	17.5	-2.9%
Maximum	4.0	3.8	-5.2%	20.7	21.1	2.2%

5.0 MODEL SCENARIOS

Several model scenarios were considered in order to estimate the impact of different conditions on DO within GBK-14 and to help inform the primary causes of low dissolved oxygen in the stream. By changing reach conditions such as increasing reaeration or decreasing SOD along the channel, these scenarios were compared to the more conservative in-stream minimum DO concentration of 5.0 mg/l which typically applies March to July. Although the calibration date is in 9/3/2016, it is a conservative approach to attain the more rigorous water quality standard (WQS) of 5.0 mg/l with a 10% margin of safety for scenario purposes.

Observed DO concentrations on 9/3/2016 were well below the conservative water quality standard of 5.0 mg/l for all hours of the day. The observed maximum was 4.0 mg/l DO, while the calibrated model estimated a maximum DO concentration of 3.8 mg/l at the calibration point. The observed and simulated minimum DO were 3.6 and 3.7 mg/l respectively which do not attain the less stringent standard of 4.0 mg/l. Scenarios were developed and compared against the more conservative water quality standard plus

a 10% margin of safety (5.5 mg/l). For all scenarios, a headwater DO concentration of 5.5 mg/L was established in order to meet the WQS with MOS along the entire reach. Based on model development, the primary causes of impairment are likely a combination of very low flows, low levels of reaeration, and high SOD compared to the rate and volume of water in the stream. The presence of nutrients, algae, and macrophytes in the system do not appear to be having a large impact due to the very small diurnal DO fluctuation observed and the relatively low concentrations of these constituents.

The list of scenarios and the resulting longitudinal DO and temperature statistics are seen below (Table 7, Figure 4). Alternative scenarios were also run for the following conditions, although none produced attainment of the WQS with MOS for the entire reach:

- Increased headwater DO concentration (headwater DO would have to be increased to greater than 15 mg/l in order for the entire reach to attain the WQS with 10% MOS)
- Increased stream shading (increased stream shade to 100% reduce water temperatures by about 3 °C and increased DO saturation by nearly 1 mg/l but did not have an impact on simulated DO)
- Decreased slow CBOD concentration (reduce CBOD from 2.5 mg/l to zero increases average instream DO by about 1%)

The scenarios which were able to attain the criteria were those involving:

- Increased reaeration (increased from 1.1 to 2.1 /d)
- Reduced SOD (decreased by half from 2.04 to 1.02 gO₂/m²/d)
- Combination of increased reaeration (increased 35%) and reduced SOD (decreased 35%)
- Increased streamflow (increased headwater streamflow from 0.038 to 0.110 m³/s)

The QUAL2K model indicates that the minimum instream DO during critical conditions is very sensitive to headwater DO concentrations, SOD rates, and intrinsic channel reaeration which is a function largely of channel slope, shape, and velocity.

		Dissolved Oxygen (mg/L)			Water Temperature (°C)		
Scenario	Description	Min	Max	Mean	Min	Мах	Mean
Observed ¹	Existing conditions	3.6	4.0	3.8	18.0	20.7	19.4
Baseline	Calibrated model	3.3	5.5	4.2	17.4	21.6	19.3
1	Increased Reaeration	5.5	6.0	5.7	17.4	21.6	19.3

6.0 TMDL ANALYSIS

Loading capacity is the allowable amount of loading from all pollutant sources that can deplete DO in GBK-14 and still meet the water quality standard of 5.0 mg/L with 10% MOS. The total maximum daily load (TMDL) uses QUAL2K to calculate the pollutant loads that can meet the DO standard.

6.1 DISSOLVED OXYGEN DEFICIT BACKGROUND

DO saturation concentration (DO_{sat}) is an important consideration when estimating assimilative capacity for DO. The value of DO_{sat} declines with increasing water temperature. In segment GBK-14, average water temperature was observed as 19.4 °C at the sampling site. DO_{sat} for this average temperature is approximately 8.96 mg/L, which means the total assimilative capacity of the stream is limited by the relationship between relatively high water temperatures and relatively low dissolved oxygen saturation. In order to achieve high concentrations of DO in water it is essential to maintain low temperatures, however low temperatures do not cause low DO, they only allow for the capacity to achieve low DO under specific conditions. The capacity of a water body to assimilate loads of pollutants that affect the oxygen balance varies as a function of water temperature. Thus, the assimilative capacity for oxygen-demanding pollutants (or other processes that deplete DO) declines with increasing temperature.

The difference between DO_{sat} and the actual DO concentration is known as the dissolved oxygen deficit (DOD). DOD is a measure of the impacts of all DO-depleting sources and also has units of mg-DO/L. The loading capacity for DO is the difference between DO_{sat} (a function of temperature) and the water quality standard with margin of safety of 5.5 mg/L, expressed as DOD. This is the allowable amount of loading from natural conditions that is acceptable to meet water quality standards that protect beneficial use. DOD allocations are the amount of loading are the amount of loading that can be attributed to a given source (i.e., SOD or headwater inflow DO) in order to meet the water quality standard.

A high DOD indicates the presence of significant causes of DO depletion. DOD may also be negative, if DO concentration exceeds DO_{sat} (as often happens during periods of active photosynthesis in dense algal mats). The ideal situation is for DOD to be zero or close to zero. This would indicate the smallest deviation from the natural equilibrium level of DO_{sat}. Because DO_{sat} varies as a function of temperature, DOD also varies with temperature (Figure 5).

Like DO itself, DOD can be converted to a load basis by multiplying by flow:

$$DOD\left[\frac{kg}{d}\right] = (DO_{sat} - DO) [mg/L] x Q [cfs] x 2.447 [conversion factor]$$

The conversion factor is the result of the following unit conversions: seconds to days, cubic feet to liters, and milligrams to kilograms. DOD provides a basis for treatment of the different factors that alter DO in West Branch DuPage River, namely reaeration and in-stream SOD conditions.

Figure 5. Assimilative capacity as a function of DO saturation.

DOD is a useful metric to look at different sources affecting DO in GBK-14. The DOD load that meets the DO standard can be calculated for a steady-state condition. Note that QUAL2K cannot be used directly to identify precise DOD impacts of oxygen-demanding sources such as CBOD, NBOD, or algal respiration, but impacts of SOD and headwater DO which dominate the system can be estimated from model output.

6.2 COMPLIANCE WITH STANDARDS

The water quality standards for West Branch DuPage River segment GBK-14 allows a minimum of 5.0 mg/L DO from March to July and 3.5 mg/L from August to February. The sampling from September 2016 shows clear evidence of not meeting the standard from 9/4/2016 to 9/8/2016 at the Springinsguth Road sampling site (Figure 6). The measured streamflow on 9/2/2016 is about twice as high as the measured streamflow on 9/6/2016, so the extreme drop in DO is likely related to the drop in flow. For the purpose of DOD calculations, the more conservative standard of 5.0 mg/l DO with a 10% MOS will be used to estimate DOD.

Figure 6. Observed dissolved oxygen from GBK-14 relative to WQS, September 2016

The relative importance of various processes affecting oxygen levels varies according to flow conditions, and this model was constructed under assumptions that it represents baseflow critical summer conditions relative to dissolved oxygen, water temperatures, and air temperatures. The calibrated QUAL2K model was used to assess the contributions of DOD as derived from internal sources (namely SOD), and inflow sources (DO below saturation of headwater flows), while relative impacts of aquatic biota respiration and biological oxygen demands of nitrogen and carbonaceous species cannot be expressly calculated. Based on the available data, respiration from algal species is not a significant contributor of low DO.

The QUAL2K model indicates that the minimum instream DO during critical conditions is very sensitive to headwater DO concentrations, SOD rates, and intrinsic channel reaeration which is a function largely of channel slope, shape, and velocity. DOD can be calculated for the stream as a function of simulated DO relative to DOD at the WQS with MOS. Calculations of DOD are detailed below:

1. Calculating DOD at the headwaters

At the headwaters, the calibrated model has a minimum DO of 5.5 mg/l, and a DO_{sat} of 8.96 mg/l based on the water temperature of 19.4 °C. DOD can be calculated at the headwaters based on the equation presented in Section 6.1:

DOD at headwaters = $(8.96 mg/l - 5.50 mg/l) \times 1.33 cfs \times 2.44 = 11.29 kg/d$

2. Calculating DOD at the outlet

At the outlet, the calibrated model has a minimum DO of 3.26 mg/l, therefore DOD can be calculated at the outlet based on the aforementioned equation:

DOD at outlet = $(8.96 mg/l - 3.26 mg/l) \times 1.33 cfs \times 2.44 = 18.50 kg/d$

3. Calculating DOD Loading Capacity

The loading capacity for DO is the difference between DO_{sat} and the water quality standard with margin of safety of 5.5 mg/L, expressed as DOD:

DOD loading capacity = $(8.96 mg/l - 5.5 mg/l) \times 1.33 cfs \times 2.44 = 11.29 kg/d$

4. Calculating DOD Load Reductions

Because the headwaters of the QUAL2K model are set to 5.5 mg/l, it is clear that no load reduction is required at the headwaters as the DOD there and the DOD loading capacity are equivalent.

At the outlet of the stream, the difference between the simulated DOD and the DOD loading capacity is the necessary load reduction:

DOD Load Reduction =
$$18.50 \frac{kg}{d} - 11.29 \frac{kg}{d} = 7.21 \frac{kg}{d}$$

The needed DOD load reduction of 7.21 kg/d is likely due to a combination of factors within the GBK-14 system. The DOD at the headwaters meets the loading capacity of the stream, but that means the stream has no additional capacity at that point. If the headwater DO is higher or lower than simulated in the calibrated model, the load capacity at the headwaters would be higher or lower respectively. Along GBK-14, the DOD is estimated to be caused be a combination of low reaeration and the presence of SOD, along with exacerbation of existing conditions due to very low flow (only several inches of stream depth). Overall, the critical conditions in GBK-14 indicate the need for a total reduction in DOD of 7.21 kg/d, which is a reduction from the existing downstream deficit (18.50 kg/d) of about 40%. Reduction of this DOD may be attained by the implementation of any of the Scenarios 1 through 4 described in Section 5.0.

1.0 INTRODUCTION

Spring Brook #1 is located within the Chicago metropolitan area, largely within the city of Wheaton in DuPage County, Illinois. Spring Brook flows southwest to join the West Branch DuPage River flowing further south to the DuPage River and Illinois River. Spring Brook #1 is composed of an upstream reach (GBKA) and a downstream reach (GBKA-01). Spring Brook's headwaters are found in northeast Wheaton, however the perennial reach appears to begin at the upstream end of GBKA at West Elm Street. River segment GBKA of Spring Brook is impaired for low dissolved oxygen (DO) concentrations, and extends approximately 1.7 miles (2.75 kilometers) downstream from West Elm Street near Kelly Park in Wheaton to the road crossing of Creekside Drive near Madison Elementary School (Figure 1). The water quality standard for DO for this reach varies throughout the year, with a minimum concentration requirement of 5.0 mg/l from March to July, and 3.5 mg/l from August to February according to the Illinois Environmental Protection Agency.

QUAL2K is a one-dimensional steady-state river water quality model frequently used for simulating DO (Chapra et al., 2012). QUAL2K assumed a well-mixed stream channel (both vertically and laterally), and employs a diel, or 24-hour period, heat budget which can be used to model DO on an hourly basis. A QUAL2K model was developed and calibrated to DO data for Spring Brook #1 segment GBKA which was measured in late July 2016. The model was setup and calibrated based on data availability for 7/27/2016. Model parameterization and assumptions were based on a combination of observed flow and water quality data as well as best professional judgement.

Figure 1. Spring Brook #1 in Wheaton, DuPage County, Illinois

2.0 QUAL2K MODEL SETUP

2.1 MODEL SEGMENTATION AND REACH INPUTS

The Spring Brook #1 segment of-interest GBKA was subdivided into two model reaches. Each model reach was assigned specific hydraulic properties developed from site surveying observations at single locations along each reach. The river was segmented at its halfway point, and elevation data were assigned using a 3-meter digital elevation model (DEM) obtained from USDA Data Gateway. Each model reach is further broken down into computational elements. Table 1 and Figure 1 summarize the reach segmentation and hydraulic properties for GBKA. The DuPage River Salt Creek Workgroup (DRWCW) conducted water quality sampling and surveying at two sites, WBWS1 and WBWS near the upstream and downstream extents of segment GBKA respectively (Figure 1).

Model Input	Reach 1 (Upstream)	Reach 2 (Downstream)
Description	Spring Brook #1 from W Elm Street	Illinois Prairie Path (Aurora
	and Kelly Park to Illinois Prairie	Branch) Crossing to Creekside
	Path (Aurora Branch) Crossing	Drive crossing near Madison
	near the Chicago Golf Club	Elementary School
Reach Length (km)	1.38	1.38
Number of 0.1-km Elements	14	14
Upstream Elevation (m)	220.37	219.53
Downstream Elevation (m)	219.53	218.69
Hydraulic Model	Manning Formula	Manning Formula
Channel Slope	0.0006	0.0001
Manning's "n"	0.024	0.080
Bottom Width (m)	5.18	7.32
Side Slopes	0.00	0.00

Table 1. Reach segmentation for GBKA QUAL2K model

Stream hydraulics were simulated using the Manning Formula for both model reaches. QUAL2K approximates stream flow using the following input parameters for this hydraulic model: channel slope, Manning's "n", bottom width, and channel side slopes. Cross sections were measured on 7/27/2016 at both sampling locations WBWS1 (upstream, reach 1), and WBWS (downstream, reach 2). The upstream cross section was measured to have a width of 17 feet (5.18 meters) and an average depth of 4.3 inches (0.11 meters), and the downstream cross section was measured to have a width of 24 feet (7.32 meters) and an average depth of 12.31 inches (0.31 meters). Given how shallow these reaches are, and the lack of precision surveying throughout the reach, rectangular channels were assumed (side slopes of zero). Channel slopes were approximated based on elevation data as well as anecdotal evidence of very low water velocity at the downstream end of the reach. Manning's "n" roughness coefficients were determined through calibration in order to meet the approximate measurements of water depth and flow velocity.

Inputs related to bottom algae coverage and prescribed reaeration rates drive diurnal DO cycling within the system, so those parameters were developed during the model calibration process (Table 2). Instream DO concentrations are very sensitive to sediment oxygen demand (SOD), for which the prescribed bottom coverage percentage and rate work in tandem to approximate. SOD monitoring was conducted along the West Branch DuPage River during the Illinois EPA Stage 2 TMDL process in 2009. SOD was measured by CDM at Hanover Park, which was temperature-corrected to an observed SOD of 2.04 g/m²/d. Given that there are no point sources discharging along Spring Brook #1, SOD rates were adjusted during the calibration process, using the 2.04 g/m²/d as an upper bound. SOD rates have been reported from 0.56 to 8.08 g/m²/d in northeastern Illinois (Butts, 1974). The sediment diagenesis model computes SOD and nutrient fluxes in-stream in addition to the prescribed SOD rate and coverage observed under existing conditions. Note that most other reach rate inputs were estimated and identified based on in-stream calibration efforts (Table 2).

Parameter	Input	Notes
Prescribed Reaeration (/d)	Reach 1: 2.00	Adjusted during calibration
	Reach 2: 0.025	
Bottom Algae Coverage	85%	Adjusted during calibration
Bottom SOD Coverage	100%	Assumed entire streambed subject to SOD
Prescribed SOD (g/m ² /d)	Reach 1: 0.40	Adjusted during calibration
	Reach 2: 2.10	
Slow CBOD Hydrolysis and Oxidation Rates (/d)	0.00	There is no change in CBOD

Parameter	Input	Notes
Phytoplankton Death Rate (/d), Settling Velocity (/d)	0.01, 0.001	measurements from upstream to downstream
Bottom Algae Max Growth Rate (/d)	600	Adjusted in tandem during calibration. Field sampling
Bottom Algae Respiration Rate (/d)	0.05	efforts on the calibration date
Bottom Algae Excretion Rate (/d)	0.05	describe limited algal growth,
Bottom Algae Death Rate (/d)	0.10	although abundant periphyton growth and filamentous algae
Bottom Algae Growth Model	Zero-Order	were observed earlier in the week.

2.2 LIGHT AND HEAT RATES

For the most part, light and heat parameters were held at model default values. The solar shortwave radiation model chosen was the Ryan-Stolzenbach, with an atmospheric transmission coefficient of 0.70, both of which were chosen during model calibration to observed water temperatures. The atmospheric longwave emissivity model chosen through calibration as well as the Brutsaert model which can be appropriate for calculating air emissivity in warm conditions. Through calibration, the wind speed function for evaporation and air convection/conduction was chosen to be Adams 1 which is used to estimate the impact of wind on air and water temperatures.

2.3 METEOROLOGICAL INPUTS

Metrological inputs to the QUAL2K model are air temperature, dew point temperature, wind, cloud cover, and shade (Table 3). All of these parameters aside from shade were supplied to the model from hourly observed data on the calibration date of 7/27/2016 recorded at the nearby West Chicago DuPage Airport (NOAA WBAN 94892). Wind speeds were measured at a height of 10 meters, so they were estimated at a height of 2 meters for QUAL2K model input based on the wind profile power law for neutral stability conditions:

Wind speed at 2 meters = (Wind speed at 10 meters)
$$*\left(\frac{2}{10}\right)^{0.143}$$
.

Meteorological inputs were identical for both reaches, except for shade which was estimated for each reach based on aerial imagery and calibrated based on observed water temperatures. Reach 1 is generally well-shaded by riparian vegetation, while Reach 2 sees some reach widening, and exposed channel, especially where sampling occurred near Madison Elementary School.

 Table 3. Meteorological inputs for model date 7/27/2016

2.4 HEADWATER INPUTS AND INITIAL CONDITIONS

Water quality sampling at sites WBWS1 and WBWS near the upstream and downstream extents of segment GBKA were used to parameterize and calibrate the model. The headwaters of Spring Brook #1 are represented by observed water quality data from sampling site WBWS1 which is within the upstream model reach. From where stream segment GBKA originates below West Elm Street near Kelly Park, the stream is heavily shaded for almost the entire reach, and there are no point source inflows, therefore the water quality from WBWS1 is considered a reasonable approximation for headwater conditions (Table 4). Within the model, the downstream extent was not a prescribed boundary. There were also no diffuse or point sources included in this model.

Parameter	Model Input	Source/Reference
Flow Rate (m ³ /s)	0.123	Estimated as product of surveyed channel area (0.55 m ²) and measured flow velocity (0.224 m/s) at WBWS1
Elevation (m)	220.40	Estimated using DEM
Hydraulic Model	Manning Formula	Inputs same as Reach 1
Water Temperature (°C)	See Table 5	Observed hourly data from WBWS1
Conductivity (µmhos)	See Table 5	Observed hourly data from WBWS1

Table 5. Observed hourly water quality constituents on 7/27/2016 at WBWS1 and WBWS

3.0 QUAL2K MODEL RESULTS

Based on the model setup detailed above, the QUAL2K model was built for Spring Brook #1 segment GBKA. The model was calibrated to DO concentrations and water temperature measured every hour at the downstream segment (model element 14 of reach 2) on the calibration date of 7/27/2016. To the extent possible, other water quality parameters and various nutrients such as total nitrogen and total phosphorus observed at the downstream end of the model extent were attempted to be calibrated to as well, although these constituents were not a priority, had limited data, and were not drivers of either water temperature or DO in this system.

3.1 MODEL RESULTS

A reasonable fit between the observed DO data and the QUAL2K simulated DO concentrations was achieved based on the aforementioned setup. The observed DO minimum, maximum, average, and median were achieved in the model results quite well, which suggests that the model adequately approximates the system based on the available data (Table 6, Figure 2). There is also a good fit between modeled and observed water temperature. Note that the observed diel dissolved oxygen concentrations do not produce a smooth curve, and that may be due to any number of factors that could cause a decrease in photosynthesis such as clouds passing overhead, leaf matter being trapped in the vicinity of the sensor, or any other type of atypical shading influence to the area. The timing of the simulated water temperature peak aligns with the observed air temperature peak during the day rather than the observed water temperature peak, and the simulated dissolved oxygen peak is a product of the relative coarseness of the model simulation.

The longitudinal changes in dissolved oxygen as compared with observed data are depicted in Figure 3. In general there is a decrease in DO occurring along the reach length due to the decrease in shade along the stream which leads to increased water temperatures.

Statistic	Observed DO	Modeled DO	Percent Error in DO	Observed Water Temperature	Modeled Water Temperature	Percent Error in Temperature
Minimum	3.16	3.11	1.62%	20.55	19.40	5.57%
Maximum	4.75	4.79	0.79%	25.45	25.86	-1.62%
Average	3.77	3.78	-0.32%	22.71	22.26	1.99%

Figure 2. Observed and modeled diel DO and water temperature results, Reach 2 Element 14

Figure 3. Modeled and observed average, minimum, and maximum dissolved oxygen concentrations along the entire model extent

Model calibration was achieved based on prioritization of measured hydraulics, diel water temperature, and diel dissolved oxygen data. Observed water velocity at the upstream end of the model and average water depth at both up and downstream sampling sites were achieved during model calibration. Observed concentrations of CBOD and chlorophyll-a were identical at both upstream and downstream sampling sites, and model calibration did achieve proper simulation of those conditions. Calibration of nutrient concentrations was achieved where possible, but given the relatively small amount of data and coarseness of the model environment, not all relative increases or decreases along the longitudinal model extent were simulated (Table 7). For example, the relative increase in ammonia and decrease in organic nitrogen observed along the model extent cannot be achieve easily because the relationship between the two constituents are simulated in tandem.

Parameter	Upstream WBWS1 Observed on 7/27/16 (weekly observed range)	Downstream WBWS Observed on 7/27/16 (weekly observed range)	Average simulated downstream results

Table 7. Observed and simulated water quality data

4.0 MODEL SCENARIOS

Several model scenarios were considered in order to estimate the impact different conditions on dissolved oxygen within Spring Brook #1 segment GBKA. By changing reach conditions such as increased stream shade or reaeration of the channel, these scenarios were compared to the in-stream minimum DO concentration of 5.0 mg/l. Pollutant load reductions for CBOD, ammonia, and phosphorus were not included in the scenarios because the model and data do not suggest that these pollutants are causing impairment. Reductions in SOD are included in the scenarios.

Observed DO concentrations on 7/27/2016 were below the water quality standard of 5.0 mg/l for almost all hours of the day. The observed minimum was 3.16 mg/l DO, while the calibrated model estimated a minimum DO concentration of 3.12 mg/l. Given that the standard is currently not met in Reach 2 of this model under existing conditions, scenarios were developed under which the standard may possibly be met. The list of scenarios and the statistics associated with diel output at Reach 2 Element 14 as compared with observed data and calibrated model results are seen below (Table 8, Figure 4). Note that increased shade alone does not increase dissolved oxygen very much (Scenario 1), but rather in-stream SOD, reaeration, and headwater DO concentrations have the greatest impact on downstream diel DO.

		Dissolv	Dissolved Oxygen (mg/L)			emperatur	e (deg C)
Scenario	Description	Min	Max	Mean	Min	Max	Mean
Observed	Existing conditions	3.16	4.75	3.77	20.55	25.45	22.71
Baseline	Calibrated model	3.11	4.79	3.78	19.40	25.86	22.26
1	Shade increased to 100% at all hours for both reaches	3.29	3.96	3.72	18.80	20.69	19.86
2	Headwater DO concentrations increased by 2.4 mg/l every hour	5.01	6.73	5.71	19.40	25.86	22.86
3	Sediment oxygen demand rate and coverage decreased to 0.4 g/m2/d and 50% respectively	5.03	6.77	5.73	19.40	25.86	22.26
4	Increased Reach 2 reaeration to 1.85 /d	5.03	5.89	5.38	19.40	25.86	22.26
5	Reach 2 SOD coverage and rate decreased by half, and Reach 2 reaeration increased to 0.3 /d	5.02	6.59	5.65	19.40	25.86	22.26

5.0 TMDL ANALYSIS

5.1 DISSOLVED OXYGEN

The DO loading capacity and allocations are the allowable amount of loading from all sources that can deplete DO in Spring Brook from its natural state compared to the DO water quality standard of 5.0 mg/L. This is expressed as the dissolved oxygen deficit (DOD). The TMDL uses QUAL2K model results to calculate the pollutant loads that can meet the DO criteria.

5.1.1 Dissolved Oxygen Deficit Background

DO saturation concentration (DO_{sat}) is an important consideration when estimating assimilative capacity for DO. The value of DO_{sat} declines with increasing water temperature. In order to achieve high concentrations of DO in water it is essential to maintain low temperatures. In addition, the capacity of a water body to assimilate loads of pollutants that affect the oxygen balance varies as a function of water temperature. Thus, the assimilative capacity for oxygen-demanding pollutants (or other processes that deplete DO) declines with increasing temperature.

The difference between DO_{sat} and the actual DO concentration is known as the dissolved oxygen deficit (DOD). A high DOD indicates the presence of significant causes of DO depletion. DOD may also be negative, if DO concentration exceeds DO_{sat} (as often happens during periods of active photosynthesis in dense algal mats), which indicates supersaturated conditions. The ideal situation is for DOD to be zero or close to zero. This would indicate the smallest deviation from the natural equilibrium level of DO_{sat}. Because DO_{sat} varies as a function of temperature, DOD also varies with temperature (Figure 6).

Like DO itself, DOD can be converted to a load basis by multiplying by flow:

$$DOD\left[\frac{kg}{d}\right] = (DO_{sat} - DO) [mg/L] x Q [cfs] x 2.447 [conversion factor]$$

The conversion factor is the result of the following unit conversions: seconds to days, cubic feet to liters, and milligrams to kilograms. DOD provides a basis for treatment of the different factors that alter DO in Spring Brook, namely the impact of headwater DO and in-stream SOD conditions.

Figure 6. Assimilative capacity as a function of DO saturation.

5.1.2 Analytical Framework

DOD is a measure of the impacts of all DO-depleting sources and also has units of mg-DO/L. The loading capacity for DO is the difference between DO_{sat} (a function of temperature) and the water quality standard of 5.0 mg/L, expressed as DOD. This is the allowable amount of loading from natural conditions that is acceptable to meet water quality standards that protect beneficial use. Allocations are the amount of loading that can be attributed to a given source (i.e., SOD or headwater inflow DO) in order to meet the water quality standard.

DO_{sat} varies with temperature and salinity. In Spring Brook, average water temperature was observed as 20.5 deg C at the upstream end and 21.6 deg C at the downstream end. DO_{sat} for these average temperatures is on the order of 8.76 mg/L for Spring Brook, which means the assimilative capacity of the stream is limited by the relationship between relatively high water temperatures and relatively low dissolved oxygen saturation.

DOD is a useful metric to look at different sources affecting DO in Spring Brook, namely SOD and headwater inflow DO. The DOD load that meets the DO standard can be calculated for a steady-state condition using QUAL2K. Note that QUAL2K cannot be used directly to identify precise DOD impacts of oxygen-demanding sources such as CBOD, NBOD, or algal respiration, but impacts of SOD and headwater DO which dominate the system can be estimated from model output.

5.1.3 Compliance with Standards

The water quality standard for Spring Brook allows a minimum of 5.0 mg/L DO from March to July (standard drops to 3.5 mg/L August to February). The limited sampling shows clear evidence of DO exceedance from 7/26/2016 to 7/28/2016 at the downstream location (Figure 7).

Figure 7. Observed DO at two sampling sites relative to WQS, summer 2016

The relative importance of various processes affecting oxygen levels varies according to flow conditions, and this model was constructed under assumptions that it represents baseflow critical summer conditions relative to dissolved oxygen, water temperatures, and air temperatures. The calibrated QUAL2K model was used to assess the contributions of DOD as derived from internal sources (namely SOD), and inflow sources (DO below saturation of headwater flows), while relative impacts of aquatic biota respiration and biological oxygen demands of nitrogen and carbonaceous species were approximated.

The QUAL2K model indicates that the minimum instream DO during critical conditions is very sensitive to headwater DO concentrations, SOD rates, and intrinsic channel reaeration which is a function largely of channel slope, shape, and velocity. DOD can be calculated for SOD and headwater DO for the calibrated model below (Table 9). The DOD flux from upstream can be estimated for Reach 1 as the difference between modeled DOD and SOD flux. Based on these estimates, Scenario 5 was considered for DOD calculations since reaeration and SOD are major drivers for the lack of attainment downstream at Reach 2 (Figure 8). Changes in headwater conditions for Reach 1 would also have a positive impact downstream, but since Reach 1 did not show impairment, the focus is on Reach 2.

Table 9. Calibrated model DOD calculations

Reach	Min DO (mg/L)	DO _{sat} (mg/L)	Calibrated Model DOD (kg/d)	DOD at WQS (kg/d)	DOD below WQS (kg/d)	SOD Flux (kg/d)	DOD Flux from Upstream (kg/d)
1	5.31	8.88	37.96	41.23	0 (attaining)	2.85	35.11
2	3.11	8.63	58.70	38.61	20.10	21.14	37.96

Figure 8. Calibrated model DO Deficits for Reach 1 and Reach 2

Overall, the critical conditions in Spring Brook indicate the need for a total reduction in DOD for Reach 2 of 20.10 kg/d, which is a reduction from existing conditions (58.70 kg/d) of about 34%. An entire reduction of this DOD may be attained by the implementation of Scenario 5 which includes increased reaeration (0.4 /d) and decreased SOD coverage and rate (50%, 1.05 gO2/m2/d). This scenario maintains the attainment of the WQS for Reach 1, and achieves attainment for Reach 2 (Figure 9). It is also possible to achieve the WQS for DO and the maximum allowable DOD based on that standard by exclusively decreasing SOD in Reach 2 or exclusively increased reaeration in Reach 2.

Figure 9. DO Deficits for Reach 1 and Reach 2: existing, standard, and Scenario 5

a. The Non-ILDOT MS4 WLA is categorical, see section 6.3.1 for description and Appendix J for a list of MS4s.

Appendix G

NPDES Permit Special Conditions

Draft DuPage/Salt Creek Special NPDES Permit Condition XX.

- The Permittee shall participate in the DuPage River Salt Creek Workgroup (DRSCW). The Permittee shall work with other watershed members of the DRSCW to determine the most cost effective means to remove dissolved oxygen (DO) and offensive condition impairments in the DRSCW watersheds.
- 2. The Permittee shall ensure that the following projects and activities set out in the DRSCW Implementation Plan (April 16, 2015), are completed (either by the permittee or through the DRSCW) by the schedule dates set forth below; and that the short-term objectives are achieved for each by the time frames identified below:

Project Name	Completion Date	Short Term Objectives	Long Term Objectives
Oak Meadows Golf Course Dam removal	December 31, 2016 (Completed)	Improve DO	Improve fish passage
Oak Meadows Golf Course stream restoration	December 31, 2017	Improve aquatic habitat (QHEI), reduce inputs of nutrients and sediment	Raise miBi
Fawell Dam modification	December 31, 2018	Modify dam to allow fish passage	Raise fiBi upstream of structure
Spring Brook restoration and dam removal	December 31, 2019	Improve aquatic habitat (QHEI), reduce inputs of nutrients and sediment	Raise miBi and fiBi
Fullersburg Woods Dam modification concept plan development	December 31, 2016 (Completed)	Identify conceptual plan for dam modification and stream restoration	Build consensus among plan stakeholders
Fullersburg Woods Dam modification	December 31, 2021	Improve DO, improve aquatic habitat (QHEI)	Raise miBi and fiBi
Fullersburg Woods Dam modification area stream restoration	December 31, 2022	Improve aquatic habitat (QHEI), reduce inputs of nutrients and sediment	Raise miBi and fiBi
Southern West Branch physical enhancement	December 31, 2022	Improve aquatic habitat (QHEI)	Raise miBi and fiBi

Southern East Branch stream enhancement	December 31, 2023	Improve aquatic habitat (QHEI), reduce inputs of nutrients and sediment	Raise miBi and fiBi
QUAL 2K East Branch and Salt Creek	December 31, 2023	Collect new baseline data and update model	Quantify improvements in watershed. Identify next round of projects for years beyond 2024.
NPS Phosphorus Feasibility Analysis	December 31, 2021	Assess NPS performance from reductions leaf litter and street sweeping	Reduce NPS contributions to lowest practical levels

- 3. The Permittee shall participate in implementation of a watershed Chloride Reduction Program, either directly or through the DRSCW. The program shall work to decrease DRSCW watershed public agency chloride application rates used for winter road safety, with the objective of decreasing watershed chloride loading. The Permittee shall submit an annual report on the annual implementation of the program identifying the practices deployed, chloride application rates, estimated reductions achieved, analyses of watershed chloride loads, precipitation, air temperature conditions and relative performance compared to a baseline condition. The report shall be provided to the Agency by March 31 of each year reflecting the Chloride Abatement Program performance for the preceding year (example: 2015-16 winter season report shall be submitted no later than March 31, 2017). The Permittee may work cooperatively with the DRSCW to prepare a single annual progress report that is common among DRSCW permittees.
- 4. The Permittee shall submit an annual progress report on the projects listed in the table of paragraph 2 above to the Agency by March 31 of each year. The report shall include project implementation progress. The Permittee may work cooperatively with the DRSCW to prepare a single annual progress report that is common among DRSCW permittees.
- 5. The Permittee shall develop a written Phosphorus Discharge Optimization Plan. In developing the plan, the Permittee shall evaluate a range of measures for reducing phosphorus discharges from the treatment plant, including possible source reduction measures, operational improvements, and minor low cost facility modifications that will optimize reductions in phosphorus discharges from the wastewater treatment facility. The permittee's evaluation shall include, but not necessarily be limited to, an evaluation of the following optimization measures:
 - a. WWTF influent reduction measures.
 - i. Evaluate the phosphorus reduction potential of users.
 - ii. Determine which sources have the greatest opportunity for reducing phosphorus (e.g., industrial, commercial, institutional, municipal, and others).

1. Determine whether known sources (e.g., restaurant and food preparation) can adopt phosphorus minimization and water conservation plans.

2. Evaluate implementation of local limits on influent sources of excessive phosphorus.

b. WWTF effluent reduction measures.

i. Reduce phosphorus discharges by optimizing existing treatment processes without causing non-compliance with permit effluent limitations or adversely impacting stream health.

1. Adjust the solids retention time for biological phosphorus removal.

2. Adjust aeration rates to reduce DO and promote biological phosphorus removal.

3. Change aeration settings in plug flow basins by turning off air or mixers at the inlet side of the basin system.

4. Minimize impact on recycle streams by improving aeration within holding tanks.

5. Adjust flow through existing basins to enhance biological nutrient removal.

6. Increase volatile fatty acids for biological phosphorus removal.

6. Within 24 months of the effective date of this permit, the Permittee shall finalize the written Phosphorus Discharge Optimization Evaluation Plan and submit it to IEPA. The plan shall include a schedule for implementing all of the evaluated optimization measures that can practically be implemented and include a report that explains the basis for rejecting any measure that was deemed impractical. The schedule for implementing all practical measures shall be no longer than 36 months after the effective date of this permit. The Permittee shall implement the measures set forth in the Phosphorus Discharge Optimization Plan in accordance with the schedule set forth in that Plan. The Permittee shall modify the Plan to address any comments that it receives from IEPA and shall implement the modified plan in accordance with the schedule therein.

Annual progress reports on the optimization of the existing treatment facilities shall be submitted to the Agency by March 31 of each year beginning 24 months from the effective date of the permit.

7. The Permittee shall, within 24 months of the effective date of this permit, complete a feasibility study that evaluates the timeframe, and construction and O & M costs of reducing phosphorus levels in its discharge to a level consistently meeting a limit of 1 mg/L, 0.5 mg/L and 0.1 mg/L utilizing a range of treatment technologies including, but not necessarily limited to, biological phosphorus removal, chemical precipitation, or a combination of the two. The study shall evaluate the construction and O & M costs of the different treatment technologies for these limits on a monthly, seasonal, and annual average basis. For each technology and each phosphorus discharge level evaluated, the study shall also evaluate the amount by which the Permittee's typical household annual sewer rates would increase if the Permittee constructed and operated the specific type of technology to achieve the specific phosphorus discharge level. Within 24 months of the effective date of this Permit, the Permittee shall submit to the Agency and the DRSCW a written report summarizing the results of the study.

8. Total phosphorus in the effluent shall be limited as follows:

a. If the Permittee will use chemical precipitation to achieve the limit, the effluent limitation shall be 1.0 mg/L on a monthly average basis, effective 10 years after the effective date of this permit unless the Agency approves and reissues or modifies the permit to include an alternate phosphorus reduction program pursuant to paragraph c or d below that is fully implemented within 10 years of the effective date of this permit.

b. If the Permittee will primarily use biological phosphorus removal to achieve the limit, the effluent limitation shall be 1.0 mg/L monthly average to be effective 11 years after the effective date of this permit unless the Agency approves and reissues or modifies the permit to include an alternate phosphorus reduction program pursuant to paragraph c or d below that is fully implemented within 11 years of the effective date of this permit.

c. The Agency may modify this permit if the DRSCW has developed and implemented a trading program for POTWs in the DRSCW watersheds, providing for reallocation of allowed phosphorus loadings between two or more POTWs in the DRSCW watersheds, that delivers the same results of overall watershed phosphorus point-source reduction and loading anticipated from the uniform application of the applicable 1.0 mg/L monthly average effluent limitation among the POTW permits in the DRSCW watersheds and removes DO and offensive condition impairments and meet the applicable dissolved oxygen criteria in 35 IL Adm. Code 302.206 and the narrative offensive aquatic algae criteria in 35 IL Adm. Code 302.203.

d. The Agency may modify this permit if the DRSCW has demonstrated and implemented an alternate means of reducing watershed phosphorus loading to a comparable result within the timeframe of the schedule of this condition and removes DO and offensive condition impairments and meet the applicable dissolved oxygen criteria in 35 IL Adm. Code 302.206 and the narrative offensive aquatic algae criteria in 35 IL Adm. Code 302.203.

- 9. The Permittee shall monitor the wastewater effluent, consistent with the monitoring requirements on Page 2 of this permit, for total phosphorus, dissolved phosphorus, nitrate/nitrite, total Kjeldahl nitrogen (TKN), ammonia, total nitrogen (calculated), alkalinity and temperature at least once a month. The Permittee shall monitor the wastewater influent for total phosphorus and total nitrogen at least once a month. The results shall be submitted on NetDMRs to the Agency unless otherwise specified by the Agency.
- 10. The Permittee shall submit a Nutrient Implementation Plan (NIP) for the DRSCW watersheds that identifies phosphorus input reductions by point source discharges, nonpoint source discharges and other measures necessary to remove DO and offensive condition impairments and meet the applicable dissolved oxygen criteria in 35 IL Adm. Code 302.206 and the narrative offensive aquatic algae criteria in 35 IL Adm. Code 302.203. The NIP shall also include a schedule for implementation of the phosphorus input reductions and other measures. The Permittee may work cooperatively with the DRSCW to prepare a single NIP that is common among DRSCW permittees. The NIP shall be submitted to the Agency by December 31, 2023.
