UNITED STATES ENVIRONMENTAL PROTECTION AGENCY
REGION 5
77 WEST JACKSON BOULEVARD
CHICAGO, IL 60604-3590

REPLY TO ATTENTION OF
WW-16J

January 13, 2021

Sanjay Sofat, Chief
Bureau of Water
Illinois Environmental Protection Agency
P.O. Box 19276
Springfield, Illinois 62794-9276

Dear Mr. Sofat:

The U.S. Environmental Protection Agency has completed our review of the final Total Maximum Daily Loads (TMDL) for segments within the Thorn Creek watershed (TCW), including support documentation and follow up information. The TCW is in northeastern Illinois, in Cook and Will Counties. The TCW TMDLs address impaired primary contact recreation due to excessive bacteria, impaired aquatic life use due to excessive chloride, zinc and dissolved oxygen and impaired aquatic life and aesthetic quality due to excessive nutrients (phosphorus).

EPA has determined that the TCW TMDLs meet the requirements of Section 303(d) of the Clean Water Act and EPA's implementing regulations set forth at 40 C.F.R. Part 130. Therefore, EPA approves Illinois's eight bacteria TMDLs, one chloride TMDL, six dissolved oxygen TMDLs, one total phosphorus TMDL and one zinc TMDL. The statutory and regulatory requirements, and EPA's review of Illinois's compliance with each requirement, are described in the enclosed decision document.

We wish to acknowledge Illinois's efforts in submitting these TMDLs and look forward to future TMDL submissions by the State of Illinois. If you have any questions, please contact Mr. Paul Proto, at 312-353-8657.

Sincerely,

 Digitally signed by Tera L. Fong

TMDL: Thorn Creek watershed bacteria, chloride, dissolved oxygen, phosphorus and zinc TMDLs, Cook and Will Counties, IL

Date: January 13, 2021

DECISION DOCUMENT FOR THE THORN CREEK WATERSHED TMDLS, COOK & WILL COUNTIES, IL

Section 303(d) of the Clean Water Act (CWA) and EPA's implementing regulations at 40 C.F.R. Part 130 describe the statutory and regulatory requirements for approvable TMDLs. Additional information is generally necessary for EPA to determine if a submitted TMDL fulfills the legal requirements for approval under Section 303(d) and EPA regulations, and should be included in the submittal package. Use of the verb "must" below denotes information that is required to be submitted because it relates to elements of the TMDL required by the CWA and by regulation. Use of the term "should" below denotes information that is generally necessary for EPA to determine if a submitted TMDL is approvable. These TMDL review guidelines are not themselves regulations. They are an attempt to summarize and provide guidance regarding currently effective statutory and regulatory requirements relating to TMDLs. Any differences between these guidelines and EPA's TMDL regulations should be resolved in favor of the regulations themselves.

1. Identification of Water body, Pollutant of Concern, Pollutant Sources, and Priority Ranking

The TMDL submittal should identify the water body as it appears on the State's/Tribe's 303(d) list. The water body should be identified/georeferenced using the National Hydrography Dataset (NHD), and the TMDL should clearly identify the pollutant for which the TMDL is being established. In addition, the TMDL should identify the priority ranking of the water body and specify the link between the pollutant of concern and the water quality standard (see Section 2 below).

The TMDL submittal should include an identification of the point and nonpoint sources of the pollutant of concern, including location of the source(s) and the quantity of the loading, e.g., lbs/per day. The TMDL should provide the identification numbers of the NPDES permits within the water body. Where it is possible to separate natural background from nonpoint sources, the TMDL should include a description of the natural background. This information is necessary for EPA's review of the load and wasteload allocations, which are required by regulation.

The TMDL submittal should also contain a description of any important assumptions made in developing the TMDL, such as:

- (1) the spatial extent of the watershed in which the impaired water body is located;
- (2) the assumed distribution of land use in the watershed (e.g., urban, forested, agriculture);
- (3) population characteristics, wildlife resources, and other relevant information affecting the characterization of the pollutant of concern and its allocation to sources;
- (4) present and future growth trends, if taken into consideration in preparing the TMDL (e.g., the TMDL could include the design capacity of a wastewater treatment facility); and
- (5) an explanation and analytical basis for expressing the TMDL through *surrogate measures*, if applicable. *Surrogate measures* are parameters such as percent fines and turbidity for

sediment impairments; chlorophyll *a* and phosphorus loadings for excess algae; length of riparian buffer; or number of acres of best management practices.

Comment:

Location Description/Spatial Extent:

The Thorn Creek Watershed (TCW) (HUC-8 #07120003) is located in northeastern Illinois, in Cook and Will counties, Illinois. The TCW covers 104 square miles in Illinois (approximately 66,564 acres) and approximately 3 square miles (1,920 acres) in northwestern Indiana. Surface waters in the TCW generally flow from southwest to the northeast where they empty into the Little Calumet River in southern Cook County. The TCW TMDLs address eight (8) impaired segments due to excessive bacteria, one impaired segment due to excessive chloride, six (6) impaired segments which violate dissolved oxygen water quality standards (WQS), one impaired segment due to excessive phosphorus and one impaired segment due to excessive zinc (Table 1 of this Decision Document).

Table 1: Thorn Creek Watershed impaired waters addressed by this TMDL

Land Use:

Land use in the TCW is predominantly urban land uses (58.74%) with agricultural land uses (19.18%), forested lands (18.80%), wetlands (1.62%) and other land uses (1.65%) (Table 2 of this Decision Document).

Table 2: Thorn Creek Watershed Land Cover - based on Illinois Gap Analysis Project (IL-GAP)

IL GAP Classification	Acreage	Percentage
<i>Urban Land Use</i>		
Urban and built up land: Urban open space	17,100	25.69%
Urban and built up land: Low/medium density (medium)	14,000	21.03%
Urban and built up land: Low/medium density (low)	4,000	6.01%
Urban and built up land: High density	4,000	6.01%
Urban and built up land TOTALS	39,100	58.74%
<i>Agricultural Land Use</i>		
Agricultural land: Corn	5,000	7.51%
Agricultural land: Soybeans	4,500	6.76%
Agricultural land: Rural grassland	3,000	4.51%
Agricultural land: Other small grains and hay	250	0.38%
Agricultural land: Winter Wheat	11	0.02%
Agricultural land: Other Agriculture	7	0.01%
Agricultural land TOTALS	12,768	19.18%
<i>Forested Land Use</i>		
Forested land: Partial canopy/Savanna upland	4,700	7.06%
Forested land: Upland (Mesic)	4,600	6.91%
Forested land: Upland (Dry Mesic)	3,200	4.81%
Forested land: Deep Marsh	16	0.02%

Other TOTALS	1,100	1.65%
<i>Total Land Use</i>		
ALL TOTALS	66,564	100.00%

Problem Identification:

Bacteria TMDLs: The eight impaired segments identified in Table 1 of this Decision Document were included on the 2016 Illinois 303(d) list due to excessive bacteria. Water quality monitoring within the TCW indicated that these segments were not attaining their designated aquatic recreation uses due to exceedances of the bacteria criteria. Excessive bacteria can negatively impact recreational uses (e.g.,

swimming, wading, boating, fishing etc.) and public health. At elevated levels, bacteria may cause illness within humans who have contact with or ingest bacteria laden water. Recreation-based contact can lead to ear, nose, and throat infections, and stomach illness.

Chloride TMDL: The Thorn Creek (HBD-04) chloride impaired segment identified in Table 1 of this Decision Document was included on the 2016 Illinois 303(d) list due to excessive chloride. Water quality monitoring within the TCW indicated that this segment was not attaining its designated aquatic life uses due to high chloride concentrations and the negative impact of those conditions on aquatic life (i.e., fish and macroinvertebrate communities).

Low levels of chloride can be found naturally in lakes and streams. Chloride is essential for aquatic life to carry out a range of biological functions. However, high concentrations of chloride in the water column can harm cellular osmotic processes in aquatic organisms. If elevated concentrations of chloride persist in the water column, aquatic life such as fish, invertebrates and even some plant species may become stressed and/or die.

High levels of salt can also negatively affect groundwater and drinking water supplies, pets, wildlife, soils, infrastructure and vehicles.

Ammonia-N (nitrogenous oxygen demand, NBOD), total phosphorus (TP), carbonaceous biochemical oxygen demand (CBOD) & sediment oxygen demand (SOD) – dissolved oxygen TMDLs: The six impaired segments identified in Table 1 of this Decision Document were included on the 2016 Illinois 303(d) list due to low concentrations of dissolved oxygen (DO) and the negative impact of those conditions on aquatic life (i.e., fish and macroinvertebrate communities). The Illinois Environmental Protection Agency (IEPA) targeted ammonia-N (NBOD), total phosphorus, CBOD & SOD as the main factors influencing dissolved oxygen concentrations in the water column of the TCW. Therefore, IEPA targeted these parameters in the development of TMDLs to address the DO impairments in the TCW.

Low dissolved oxygen concentrations can negatively impact aquatic life use. The decreases in dissolved oxygen can stress benthic macroinvertebrates and fish. Increased turbidity, brought on by elevated levels of nutrients within the water column, can reduce dissolved oxygen in the water column, and cause large shifts in dissolved oxygen concentrations and pH in the water column throughout the day. Shifting chemical conditions within the water column may stress aquatic life. In some instances, degradations in aquatic habitats or water quality have reduced/alterd fish communities from those communities which support sport fish species to communities which support more tolerant rough fish species.

Biological processes associated with the breakdown and conversion of organic carbon to carbon dioxide are measured by CBOD. SOD is a measure of the oxygen depletion of biological and chemical processes in sediment (e.g., the aerobic decay of organic materials in stream sediments). Both CBOD and SOD remove oxygen from the water column at the sediment/water column interface.

Typically, TMDLs are developed to address a specific pollutant causing an impairment. For the waters impaired by low DO, IEPA determined that the low DO impairment was due to complex biological and chemical interactions occurring in the sediment and water column (Section 2.3.5 of the final TMDL document). These processes were modeled using the QUAL2K model and represented as the NBOD, CBOD, SOD, and TP loads in Tables 9 and 10 of this Decision Document. IEPA explained that the

ammonia (NBOD) component of the four dissolved oxygen-demanding parameters (i.e., NBOD, TP, CBOD and SOD) was the primary focus of the TMDL and that ammonia WLA are consistent with current NPDES permit limits (Table 2-30 of the final TMDL document).¹ However, attaining the loads assigned to CBOD, TP, and SOD are important for meeting the dissolved oxygen water quality standards, and IEPA included actions and activities that will reduce these dissolved oxygen-demanding substances in Section 3 of the final TMDL document.

Total phosphorus TMDL: Sauk Trail Lake (RHI) identified in Table 1 of this Decision Document was included on the 2016 Illinois 303(d) list due to excessive nutrients (phosphorus). Water quality monitoring demonstrated that Sauk Trail Lake was not attaining its designated aquatic life and aesthetic quality uses due to excessive nutrients. Water quality monitoring within the TCW was completed at several locations and the data collected during these efforts served as the foundation for modeling efforts completed in this TMDL study.

While TP is an essential nutrient for aquatic life, elevated concentrations of TP can lead to nuisance algal blooms that negatively impact aquatic life and recreation (e.g., swimming, boating, fishing, etc.). Algal decomposition depletes dissolved oxygen levels within the water column. The decreases in dissolved oxygen can stress benthic macroinvertebrates and fish. Depletion of oxygen in the water column can also lead to conditions where phosphorus is released from bottom sediments (i.e., internal loading). Also, excess algae can shade the water column which limits the distribution of aquatic vegetation. Aquatic vegetation stabilizes bottom sediments and is an important habitat for macroinvertebrates and fish.

Zinc TMDL: The Thorn Creek impaired segment (HBD-02) identified in Table 1 of this Decision Document was included on the 2016 Illinois 303(d) list due to excessive zinc measured in the water column. Excessive zinc within the water column may harm aquatic species such as fish and macroinvertebrates. Certain metals species dissolve in water and may be absorbed by fish and other aquatic organisms. Small concentrations of certain dissolved metals may be, in the short term, toxic to aquatic species and, in the long term, may bioaccumulate in the tissue of certain aquatic species.

Priority Ranking:

The water bodies addressed by the TCW TMDLs were given a priority ranking for TMDL development due to: the impairment impacts on aquatic life, recreation, aesthetic quality, the public value of the impaired water resource and the timing of TMDL development as it pertains to the Illinois basin monitoring process.

Pollutants of Concern:

The pollutants of concern are: bacteria (fecal coliform), chloride, ammonia-N (NBOD), CBOD and SOD for the dissolved oxygen impaired water bodies, nutrients (TP) and zinc.

¹ Illinois EPA and EPA discussion on January 6, 2021.

Source Identification (point and nonpoint sources):

Point Source Identification: The potential point sources to the TCW are:

TCW bacteria TMDLs:

National Pollutant Discharge Elimination Systems (NPDES) permitted facilities: NPDES permitted facilities may contribute bacteria loads to surface waters through discharges of treated wastewater. Permitted facilities must discharge treated wastewater according to their NPDES permit. IEPA determined that there are six NPDES permitted facilities in the TCW which contribute bacteria from treated wastewater releases (Table 3 of this Decision Document). IEPA assigned each of these facilities a portion of the bacteria wasteload allocation (WLA).

Table 3: NPDES facilities which contribute pollutant loading in the Thorn Creek Watershed TMDLs

Facility Name	Permit #	Impaired Reach
Fecal coliform TMDLs		
Thorn Creek Basin Sanitary District STP	IL0027723	HBD-06

Municipal Separate Storm Sewer (MS4): There are a number of MS4 communities which contribute stormwater runoff to surface waters in the TCW. Stormwater from MS4s can transport bacteria to surface water bodies during or shortly after storm events. IEPA identified MS4 permittees in the TCW (Table 4 of this Decision Document) which were assigned a portion of the WLA.

Table 4: MS4 communities which contribute pollutant loading in the Thorn Creek Watershed TMDLs

Concentrated Animal Feedlot Operations (CAFOs): IEPA determined that the TCW does not have CAFOs which contribute bacteria to waters of the TCW.

Combined Sewer Overflows (CSOs) and Sanitary Sewer Overflows (SSOs): IEPA determined that the TCW does not have CSOs nor SSOs which contribute bacteria to waters of the TCW.

TCW chloride TMDL:

NPDES permitted facilities: NPDES permitted facilities may contribute chloride loads to surface waters through discharges of treated wastewater. Permitted facilities must discharge treated wastewater according to their NPDES permit. IEPA determined that there is one facility, the Thorn Creek Basin Sanitary District STP (IL0027723), which contributes chloride from treated wastewater releases (Table 3 of this Decision Document). IEPA assigned this facility a portion of the chloride WLA.

MS4 Community inputs: There are a number of MS4 communities (Table 4 of this Decision Document) which contribute stormwater flow to waters in TCW. Road salt usage via municipal operators and private applicators (e.g., private citizens and commercial contractors salting parking lots, sidewalks and other pedestrian/automobile usage areas) are some of the main sources of chloride which impact chloride loading contributions in the TCW. Chloride from these sources is carried into surface waters during snowmelt or rainfall runoff events via impervious surfaces (e.g., highways, roads and other paved areas) connected to MS4 stormwater infrastructure.

TCW Ammonia-N (NBOD)/TP/CBOD/SOD - dissolved oxygen TMDLs:

NPDES permitted facilities: NPDES permitted facilities may contribute ammonia loads (i.e., ammonia-N, NBOD) to surface waters through discharges of treated wastewater. Permitted facilities must discharge treated wastewater according to their NPDES permit. IEPA determined that there are two NPDES permitted facilities, the Thorn Creek Basin Sanitary District STP (IL0027723) and the Paradise Park Mobile Home Park (IL0026794) in the TCW which contribute ammonia from treated

wastewater releases (Table 3 of this Decision Document). IEPA assigned each of these facilities a portion of the ammonia WLA.

MS4 Community inputs: Stormwater from MS4s can transport ammonia to surface water bodies during or shortly after storm events. IEPA identified several MS4 permittees in the TCW (Table 4 of this Decision Document) which were assigned a portion of the ammonia WLA.

TCW phosphorus TMDLs:

MS4 Community inputs: Stormwater from MS4s can transport phosphorus to surface water bodies during or shortly after storm events. IEPA identified five MS4 permittees in the TCW (Table 4 of this Decision Document) which were assigned a portion of the phosphorus WLA.

TCW zinc TMDL:

NPDES permitted facilities: NPDES permitted facilities may contribute zinc loads to surface waters through discharges of treated wastewater. Permitted facilities must discharge treated wastewater according to their NPDES permit. IEPA assigned a zinc WLA to the Aqua Illinois- University Park Wastewater Treatment Plant (WWTP) (IL0024473).

MS4 Community inputs: Stormwater from MS4s can transport zinc to surface water bodies during or shortly after storm events. IEPA identified several MS4 permittees in the TCW (Table 4 of this Decision Document) which were assigned a portion of the phosphorus WLA.

Nonpoint Source Identification: The potential nonpoint sources to the TCW are:

TCW bacteria TMDLs:

Non-regulated urban runoff: Runoff from urban areas (e.g., urban, residential, commercial or industrial land uses) can contribute bacteria to local water bodies. Stormwater from urban areas, which drain impervious surfaces, may introduce bacteria derived from wildlife or pet droppings to surface waters.

Discharges from Septic Systems or unsewered communities: Failing septic systems are a potential source of bacteria within the TCW. Septic systems generally do not discharge directly into a water body, but effluents from septic systems may leach into groundwater or pond at the surface where they can be washed into surface waters via stormwater runoff events. Age, construction and use of septic systems can vary throughout a watershed and influence the bacteria contribution from these systems.

Stormwater from agricultural land use practices: Runoff from agricultural lands may contain significant amounts of bacteria which may lead to impairments in the TCW. Feedlots generate manure which may be spread onto fields. Runoff from fields with spread manure can be exacerbated by tile drainage lines, which channelize the stormwater flows and reduce the time available for bacteria to die-off.

Wildlife: Wildlife is a known source of bacteria in water bodies as many animals spend time in or around water bodies. Deer, geese, ducks, raccoons, and other animals all create potential sources of bacteria via contaminated runoff from animal habitats, such as urban park areas, forest, and rural areas.

TCW chloride TMDL:

Stormwater from areas not covered under a MS4 NPDES permit: Stormwater runoff from areas outside the boundaries of MS4 areas, such as non-permitted urban, residential, commercial or industrial areas, can contribute chloride to surface waters of the TCW. Non-regulated stormwater may drain impervious surfaces and add any residual chlorides from those surfaces to surface waters.

Discharges from septic systems or unsewered communities: Septic systems are a potential source of chloride within the TCW. Septic systems generally do not discharge directly into a water body, but effluents from septic systems may leach into groundwater or pond at the surface where they can be washed into surface waters via stormwater runoff events. Age, construction and use of septic systems can vary throughout a watershed and influence the chloride contribution from these systems. Water softening systems which are in areas not connected to municipal sewer lines likely discharge to septic fields and chloride contributions from those septic systems may ultimately mix with groundwater or surface water near the septic field.

Chloride contributions from agricultural lands: Chloride may be added via use of fertilizers containing chloride anions (e.g., potassium chloride (KCl)) and biosolids which are spread onto agricultural areas. Chloride may be liberated from farm fields within stormwater runoff which can be exacerbated by tile drainage lines, which channelize the stormwater flows.

TCW Ammonia-N (NBOD)/TP/CBOD/SOD - dissolved oxygen TMDLs:

Stormwater from areas not covered under a MS4 NPDES permit: Stormwater runoff from areas outside the boundaries of MS4 areas, such as non-permitted urban, residential, commercial or industrial areas, can contribute ammonia and/or nutrients to surface waters of the TCW. Non-regulated stormwater may drain impervious surfaces and add any residual ammonia and/or nutrients from those surfaces to surface waters.

Discharges from septic systems or unsewered communities: Failing septic systems are a potential source of ammonia and/or nutrients within the TCW. Septic systems generally do not discharge directly into a water body, but effluents from septic systems may leach into groundwater or pond at the surface where they can be washed into surface waters via stormwater runoff events. Age, construction and use of septic systems can vary throughout a watershed and influence the nutrient contribution from these systems.

Stormwater from agricultural land use practices: Runoff from agricultural lands may contain significant amounts of ammonia and/or nutrients which may lead to impairments in the TCW. Feedlots generate manure which may be spread onto fields. Runoff from fields with spread manure can be exacerbated by tile drainage lines, which can channelize the stormwater flows to local surface waters.

TCW phosphorus TMDL:

Stormwater from areas not covered under a MS4 NPDES permit: Stormwater runoff from areas outside the boundaries of MS4 areas, such as non-permitted urban, residential, commercial or industrial areas, can contribute nutrients, organic material and organic rich sediment during stormwater runoff events. Runoff from urban/developed areas can include phosphorus derived from fertilizers, leaf and grass litter, pet wastes, and other sources of anthropogenic derived nutrients.

Stormwater runoff from agricultural land use practices: Runoff from agricultural lands may contain significant amounts of nutrients, organic material and organic-rich sediment which may lead to impairments in the TCW. Manure spread onto fields is often a source of phosphorus, and can be exacerbated by tile drainage lines, which channelize the stormwater. Tile lined fields and channelized ditches enable particles to move more efficiently into surface waters. Phosphorus, organic material and organic-rich sediment may be added via surface runoff from upland areas which are being used for Conservation Reserve Program (CRP) lands, grasslands, and agricultural lands used for growing hay or other crops. Stormwater runoff may contribute nutrients and organic-rich sediment to surface waters from livestock manure, fertilizers, vegetation and erodible soils.

Internal loading: The release of phosphorus from lake sediments contributes internal phosphorus loading to Sauk Trail Lake. Phosphorus may build up in the bottom waters of the lake and may be resuspended or mixed into the water column when the thermocline decreases, and the lake water mixes.

Wetland and Forest Sources: Phosphorus, organic material and organic-rich sediment may be added to surface waters by stormwater flows through wetland and forested areas in the TCW. Storm events may mobilize phosphorus through the transport of suspended solids and other organic debris.

Discharges from septic systems or unsewered communities: Failing septic systems are a potential source of nutrients within the TCW. Septic systems generally do not discharge directly into a water body, but effluents from septic systems may leach into groundwater or pond at the surface where they can be washed into surface waters via stormwater runoff events. Age, construction and use of septic systems can vary throughout a watershed and influence the nutrient contribution from these systems.

Wildlife: Wildlife is a known source of nutrients in water bodies as many animals spend time in or around water bodies. Deer, geese, ducks, raccoons, and other animals all create potential sources of nutrients via contaminated runoff from animal habitats, such as urban park areas, forest, and rural areas.

TCW zinc TMDL:

Stormwater from areas not covered under a MS4 NPDES permit: Stormwater runoff from areas outside the boundaries of MS4 areas, such as non-permitted urban, residential, commercial or industrial areas, can contribute zinc to surface waters of the TCW. These areas may contribute zinc to surface waters via stormwater runoff derived from precipitation which has fallen on exposed metal in industrial areas (e.g., scrap metal piles in industrial areas). Stormwater may liberate metals and other soluble compounds and transport it into surface waters of the TCW.

Naturally occurring zinc within soils: IEPA explained that soils in the TCW may also have a higher than normal background levels of zinc. These soluble species of zinc may be transported to surface waters via overland runoff, soil erosion and groundwater. Zinc solubility is mostly influenced by pH (i.e., zinc's ability to precipitate with carbonate minerals) and organic matter (i.e., presence of clays which, under the right pH conditions may encourage greater sorption to clays).

Future Growth:

IEPA considered information gathered during the 2000 census in determining whether to assign reserve capacity (RC) to the TMDL equation to account for future growth in the TCW. Future population projections anticipate growth in the TCW. IEPA explained that it implicitly accounted for RC in its

WLA calculations (Section 2.3.1.5 of the final TMDL document) for all TMDLs. IEPA communicated that permittees in the TCW were following expected population trends and therefore had already accounted for future growth scenarios in their design and design capacity calculations. Specifically, certain permittees had utilized design maximum flows (DMF) values in place of design average flow (DAF) values, especially during high flow conditions. IEPA attributed these conservative assumptions to providing an implicit reserve capacity and allowing for the use of the entire treatment and discharge capacity available while still remaining within the WLA (Section 2.3.1.5 of the final TMDL document).

The WLA and load allocations for the TCW TMDLs were calculated for all current and future sources. Any expansion of point or nonpoint sources will need to comply with the respective WLA and load allocation (LA) values calculated in the TCW TMDLs.

The EPA finds that the TMDL document submitted by IEPA satisfies the requirements of the first criterion.

2. Description of the Applicable Water Quality Standards and Numeric Water Quality Target

The TMDL submittal must include a description of the applicable State/Tribal water quality standard, including the designated use(s) of the water body, the applicable numeric or narrative water quality criterion, and the antidegradation policy (40 C.F.R. §130.7(c)(1)). EPA needs this information to review the loading capacity determination, and load and wasteload allocations, which are required by regulation.

The TMDL submittal must identify a numeric water quality target(s) – a quantitative value used to measure whether or not the applicable water quality standard is attained. Generally, the pollutant of concern and the numeric water quality target are, respectively, the chemical causing the impairment and the numeric criteria for that chemical (e.g., chromium) contained in the water quality standard. The TMDL expresses the relationship between any necessary reduction of the pollutant of concern and the attainment of the numeric water quality target. Occasionally, the pollutant of concern is different from the pollutant that is the subject of the numeric water quality target (e.g., when the pollutant of concern is phosphorus and the numeric water quality target is expressed as Dissolved Oxygen (DO) criteria). In such cases, the TMDL submittal should explain the linkage between the pollutant of concern and the chosen numeric water quality target.

Comment:

Section 4 of the final TMDL document explains that water bodies in the TCW are not meeting their General Use designation. The Illinois Pollution Control Board (IPCB) defines General Use standards as those that:

"will protect the state's water for aquatic life, wildlife, agricultural use, secondary contact use and most industrial uses, and ensure the aesthetic quality of the state's aquatic environment."

Under the General Use classification, waters are further designated as impaired for aquatic life use, aesthetic quality use and primary contact recreational use. Table 1 of this Decision Document shows the various water body segments and their associated impaired uses.

Primary contact uses, defined as:

“any recreational or other water use in which there is prolonged and intimate contact with the water (where the physical configuration of the water body permits it) involving considerable risk of ingesting water in quantities sufficient to pose a significant health hazard, such as swimming and water skiing.” (35 Ill. Adm. Code 301.355)

are protected for all General Use waters.

The applicable General Use water quality standards for the TCW TMDL water bodies are established in Illinois Administrative Rules Title 35, Environmental Protection; Subtitle C, Water Pollution; Chapter I, Pollution Control Board; Part 302, Water Quality Standards, Subpart B. Table 5 of this Decision Document lists all of the parameters and the applicable citation under the Illinois Code.

Table 5: Water Quality Standards Applicable in the Thorn Creek watershed TMDL

Parameter	Units	Water Quality Standard	Regulatory Reference
Total Fecal Coliform ¹	# / 100 mL	400 in < 10% of samples ²	302.209
		Geometric Mean ³ < 200	
Chloride	mg/L	500	302.407
Dissolved Oxygen	mg/L	6.0 mg/L weekly average (March-July) 5.0 mg/L daily minimum (March-July) 4.0 mg/L weekly average (August-February) 3.5 mg/L daily minimum (August-February)	302.502 & 302.501
Total Phosphorus ⁴	mg/L	0.05	302.205
Zinc (dissolved)	µg/L	93	302.208(e)

¹ = Fecal Coliform standards apply only between May 1 and October 31

² = Standard shall not be exceeded by more than 10% of the samples collected during any 30-day period

³ = Geometric mean based on minimum of 5 samples taken over not more than a 30-day period

⁴ = Standard applies to inland lakes and reservoirs (greater than 20 acres) and in any stream at the point where it enters any such lake or reservoir.

Bacteria TMDL target: The fecal coliform TMDL target employed for the TCW bacteria TMDL is the **200 colony forming units (cfu) per 100 mL** (200 cfu/100 mL) portion of the standard. IEPA believes that using the 200 cfu/100 mL portion of the standard for TMDL calculations will result in the greatest bacteria reductions within the TCW and will result in the attainment of the 400 cfu/100 mL portion of the standard. While the bacteria TMDLs will focus on the geometric mean portion of the water quality standard, attainment of both parts of the water quality standard is required.

Chloride TMDL target: The chloride TMDL target for the TCW chloride TMDL is **500 mg/L**.

Ammonia-N (NBOD)/TP/CBOD/SOD – dissolved oxygen TMDL target: The dissolved oxygen TMDL target for the TCW dissolved oxygen TMDLs is **5.0 mg/L**.

Phosphorus TMDL target: The phosphorus TMDL target for the TCW phosphorus TMDL is **0.05 mg/L**.

Zinc TMDL target: The zinc TMDL target for the TCW zinc TMDL is **93 µg/L**. Zinc acute and chronic standards are based on water hardness, per the formulas in Illinois Water Quality Standards Section 302.208(e). IEPA calculated the zinc target based upon the average hardness value for all samples, and included average hardness, acute and chronic zinc calculations in Appendix F of the final TMDL document.

The EPA finds that the TMDL document submitted by IEPA satisfies the requirements of the second criterion.

3. Loading Capacity - Linking Water Quality and Pollutant Sources

A TMDL must identify the loading capacity of a water body for the applicable pollutant. EPA regulations define loading capacity as the greatest amount of a pollutant that a water can receive without violating water quality standards (40 C.F.R. §130.2(f)).

The pollutant loadings may be expressed as either mass-per-time, toxicity or other appropriate measure (40 C.F.R. §130.2(i)). If the TMDL is expressed in terms other than a daily load, e.g., an annual load, the submittal should explain why it is appropriate to express the TMDL in the unit of measurement chosen. The TMDL submittal should describe the method used to establish the cause-and-effect relationship between the numeric target and the identified pollutant sources. In many instances, this method will be a water quality model.

The TMDL submittal should contain documentation supporting the TMDL analysis, including the basis for any assumptions; a discussion of strengths and weaknesses in the analytical process; and results from any water quality modeling. EPA needs this information to review the loading capacity determination, and load and wasteload allocations, which are required by regulation.

TMDLs must take into account *critical conditions* for stream flow, loading, and water quality parameters as part of the analysis of loading capacity (40 C.F.R. §130.7(c)(1)). TMDLs should define applicable *critical conditions* and describe their approach to estimating both point and nonpoint source loadings under such *critical conditions*. In particular, the TMDL should discuss the approach used to compute and allocate nonpoint source loadings, e.g., meteorological conditions and land use distribution.

Comment:

TCW bacteria TMDLs: IEPA used the geometric mean (200 cfu/100 mL) of the bacteria (fecal coliform) WQS to calculate loading capacity values for the bacteria TMDLs. IEPA believes the geometric mean of the bacteria WQS provides the best overall characterization of the status of the watershed. EPA agrees with this assertion, as stated in the preamble of, “*The Water Quality Standards for Coastal and Great Lakes Recreation Waters Final Rule*” (69 FR 67218-67243, November 16, 2004) on page 67224, “...the geometric mean is the more relevant value for ensuring that appropriate actions are taken to protect and improve water quality because it is a more reliable measure, being less subject to random variation, and more directly linked to the underlying studies on which the 1986 bacteria criteria were based.” IEPA stated that the bacteria TMDLs will focus on the geometric mean portion of the water quality standard (200 cfu/100 mL) and that it expects that by attaining the 200 cfu/100 mL portion of the bacteria (fecal coliform) WQS the 400 cfu/100 mL portion of the bacteria (fecal coliform) WQS will also be attained. EPA finds these assumptions to be reasonable.

Typically loading capacities are expressed as a mass per time (e.g., pounds per day). However, for fecal coliform loading capacity calculations, mass is not always an appropriate measure because fecal coliform is expressed in terms of colony forming units. This approach is consistent with the EPA’s

regulations which define “load” as “an amount of matter that is introduced into a receiving water” (40 CFR §130.2). To establish the loading capacities for the TCW bacteria TMDLs, IEPA used Illinois’s WQS for fecal coliform (200 cfu/100 mL). A loading capacity is, “the greatest amount of loading that a water can receive without violating water quality standards.” (40 CFR §130.2). Therefore, a loading capacity set at the WQS will assure that the water does not violate WQS. IEPA’s bacteria (fecal coliform) TMDL approach is based upon the premise that all discharges (point and nonpoint) must meet the WQS when entering the water body. If all sources meet the WQS at discharge, then the water body should meet the WQS and the designated use.

Flow duration curves (FDC) were created for the bacteria segments in the TCW via flow data from one of five USGS gages in the TCW (Table 6 of this Decision Document).

Table 6: USGS Gages and flow data used in the calculation of flow-based TMDLs in the Thorn Creek Watershed

USGS Gage ID	USGS Gage Name	Gaged Watershed Area	Applicable Impaired Segments
		<i>square miles</i>	
USGS #05536216	Thorn Creek at Glenwood	24.7	<i>Thorn Creek</i> : HBD-03, HBD-05 & HBD-06
USGS #05536235	Deer Creek Near Chicago Heights	23.1	<i>Deer Creek</i> : HBDC & HBDC-02
USGS #05536255	Butterfield Creek at Flossmoor	23.5	<i>Butterfield Creek</i> : HBDB-03
USGS #05536265	Lansing Ditch near Lansing	8.8	<i>North Creek</i> : HBDA-01
USGS #05536275	Thorn Creek at Thornton	104.0	<i>Thorn Creek</i> : HBD-02 & HBD-04

Where available, USGS stream gages located on an impaired segment were used to estimate flows. In other cases, the closest available gage with similar watershed characteristics was used to estimate flows using the drainage area ratio (DAR) method. IEPA used the following DAR equation to estimate flows in unaged subwatersheds:

$$Q_{\text{ungaged}} = (A_{\text{ungaged}} / A_{\text{gaged}}) * Q_{\text{gaged}}$$

where,

- Q_{ungaged} = Flow at the unaged location
- Q_{gaged} = Flow at USGS gage station (e.g., #05536216)
- A_{ungaged} = Drainage area of the unaged location
- A_{gaged} = Drainage area of the USGS gage location (e.g., #05536216)

Flow data focused on dates within the recreation season (May 1 to October 31). Daily stream flows were necessary to implement the load duration curve (LDC) approach.

FDCs graphs have flow duration interval (percentage of time flow exceeded) on the X-axis and discharge (flow per unit time) on the Y-axis. The FDC were transformed into LDC by multiplying individual flow values by the WQS (200 cfu/100 mL) and then multiplying that value by a conversion factor. The resulting points are plotted onto a load duration curve graph. LDC graphs, for the TCW bacteria TMDLs, have flow duration interval (percentage of time flow exceeded) on the X-axis and bacteria (fecal coliform) concentrations (number of bacteria per unit time) on the Y-axis. The curved line on a LDC graph represents the TMDL of the respective flow conditions observed at that location.

Water quality monitoring was completed for the bacteria impaired segments of the TCW and measured fecal coliform concentrations were converted to individual sampling loads by multiplying the sample concentration by the instantaneous flow measurement observed/estimated at the time of sample collection. The individual sampling loads were plotted on the same figure with the created LDC. Individual LDCs are found in Section 1 (e.g., Figures 1-6 to 1-13) of the final TMDL document.

The LDC plots were subdivided into five flow regimes; high flow conditions (exceeded 0–10% of the time), moist flow conditions (exceeded 10–40% of the time), mid-range flow conditions (exceeded 40–50% of the time), dry flow conditions (exceeded 50–90% of the time), and low flow conditions (exceeded 90–100% of the time). LDC plots can be organized to display individual sampling loads with the calculated LDC. Watershed managers can interpret LDC graphs with individual sampling points plotted alongside the LDC to understand the relationship between flow conditions and water quality exceedances within the watershed. Individual sampling loads which plot above the LDC represent violations of the WQS and the allowable load under those flow conditions at those locations. The difference between individual sampling loads plotting above the LDC and the LDC, measured at the same flow, is the amount of reduction necessary to meet WQS.

The strengths of using the LDC method are that critical conditions and seasonal variation are considered in the creation of the FDC by plotting hydrologic conditions over the flows measured during the recreation season. Additionally, the LDC methodology is relatively easy to use and cost-effective. The weaknesses of the LDC method are that nonpoint source allocations cannot be assigned to specific sources, and specific source reductions are not quantified. Overall, IEPA believes and EPA concurs that the strengths outweigh the weaknesses for the LDC method.

Implementing the results shown by the LDC requires watershed managers to understand the sources contributing to the water quality impairment and which Best Management Practices (BMPs) may be the most effective for reducing bacteria loads based on flow magnitudes. Different sources will contribute bacteria loads under varying flow conditions. For example, if exceedances are significant during high flow events this would suggest storm events are the cause and implementation efforts can target BMPs that will reduce stormwater runoff and consequently bacteria loading into surface waters. This allows for a more efficient implementation effort.

Bacteria TMDLs for the TCW were calculated and those results are found in Table 7 of this Decision Document. The load allocations were calculated after the determination of the WLA, and the Margin of Safety (MOS) (10% of the loading capacity). Load allocations (e.g., stormwater runoff from agricultural land use practices and feedlots, septic systems, wildlife inputs etc.) were not split among individual nonpoint contributors. Instead, load allocations were combined together into a categorical LA to cover all nonpoint source contributions.

Table 7: Bacteria TMDLs for the Thorn Creek Watershed are located at the end of this Decision Document

Table 7 of this Decision Document reports multiple points (the midpoints of the designated 10% flow regime) on the loading capacity curve. However, it should be understood that the components of the TMDL equation could be illustrated for any point on the entire loading capacity curve. The LDC method

can be used to display collected bacteria monitoring data and allows for the estimation of load reductions necessary for attainment of the bacteria water quality standard. Using this method, daily loads were developed based upon the flow in the water body. Loading capacities were determined for the segment for multiple flow regimes. This allows the TMDL to be represented by an allowable daily load across all flow conditions. Table 7 of this Decision Document identifies the loading capacity for the water body at each flow regime. Although there are numeric loads for each flow regime, the LDC is what is being approved for this TMDL.

Table 7 of the Decision Document presents IEPA's loading reduction estimates for the bacteria TMDLs. These loading reductions (i.e., the percent reduction row at the bottom of each TMDL table) were calculated from field sampling data collected in the TCW. IEPA explained that its load reduction estimates are likely more conservative since they are based on a limited water quality data set.

EPA concurs with the data analysis and LDC approach utilized by IEPA in its calculation of loading capacities, wasteload allocations, load allocations and the margin of safety for the TCW bacteria TMDLs. The methods used for determining the TMDL are consistent with U.S. EPA technical memos.²

TCW chloride TMDL: IEPA developed a LDC to calculate a chloride TMDL for the Thorn Creek (HBD-04) segment. The same LDC development strategy was employed for the chloride TMDL as was used to calculate the bacteria LDC values. IEPA used flow measurements from USGS gage #05536275 on Thorn Creek near Thornton, IL and DAR calculations to calculate the flows which were used in the FDC and the LDC for the Thorn Creek (HBD-04) chloride TMDL. The FDC were transformed into LDC by multiplying individual flow values by the chloride TMDL target (500 mg/L) and then multiplying that value by a conversion factor.

A chloride TMDL was calculated (Table 8 of this Decision document) by IEPA. The LA value was calculated after the determination of the WLA, and the MOS. Load allocations (e.g., non-MS4 urban stormwater runoff) was not split among individual nonpoint contributors. Instead, load allocations were combined together into one value to cover all nonpoint source contributions. Table 8 of this Decision Document reports ten values (i.e., the midpoints of the 10-percent flow regimes) on the loading capacity curve. However, it should be understood that the components of the TMDL equation could be illustrated for any point on the entire loading capacity curve.

The LDC method can be used to display collected chloride monitoring data and allows for the estimation of load reductions necessary for attainment of the WQS. Using this method, daily loads were developed based upon the flow in the water body. Loading capacities were determined for Thorn Creek (HBD-04) for multiple flow regimes. This allows the TMDL to be represented by an allowable daily load across all flow conditions. Although there are numeric loads for each flow regime, the LDC is what is being approved for this TMDL.

Table 8: The chloride TMDL for Thorn Creek (HBD-04) of the TCW is located at the end of this Decision Document

² U.S. Environmental Protection Agency. August 2007. *An Approach for Using Load Duration Curves in the Development of TMDLs*. Office of Water. EPA-841-B-07-006. Washington, D.C.

EPA supports the data analysis and modeling approach utilized by IEPA in its calculation of WLA, LA and MOS for the chloride TMDL for Thorn Creek (HBD-04). Additionally, EPA concurs with the loading capacities calculated by the IEPA in its TCW chloride TMDL. EPA finds IEPA's approach for calculating the loading capacity for its TCW chloride TMDL to be reasonable and consistent with EPA guidance.

TCW Ammonia-N (NBOD)/TP/CBOD/SOD – dissolved oxygen TMDLs: IEPA employed QUAL2K (Appendix C of the final TMDL document) to develop the DO TMDLs in the TCW for segments HBD-02, HBD-03, HBD-04, HBD-06, HBDA-01 and HBDC-02. IEPA explained that QUAL2K is a one-dimensional stream water quality model applicable to well-mixed streams (Section 1.4.1 of the final TMDL document). The QUAL2K model assumes steady state hydraulics and allows for point source inputs, diffuse loading and tributary flows. The QUAL2K model incorporates historical water quality data, observed hydraulic information, and point source discharge data along with model defaults to predict the resulting instream DO concentrations.

IEPA used the QUAL2K model to determine load reductions of oxygen-demanding materials needed to meet the instantaneous DO minimum standard of 5.0 mg/L applicable March 1 – July 31. The QUAL2K model simulates DO dynamics as a function of nitrogenous and carbonaceous oxygen demand, atmospheric reaeration, sediment oxygen demand (SOD), and plant photosynthesis and respiration. The model also simulates the fate and transport of nutrients and biochemical oxygen demand (BOD) and the growth and abundance of floating (phytoplankton) and attached (periphyton) algae (as chlorophyll-a). USGS collected flow data from all five USGS gages in the TCW (Table 6 of this Decision Document) were used to set flow rates and to characterize hydraulic characteristics of the DO impaired segments.

IEPA performed a calibration exercise for kinetic and transport parameters in the QUAL2K model as well as a sensitivity analysis. These analyses confirmed IEPA's confidence in their model set up and provided a level of confidence to their QUAL2K modeling results.

IEPA calculated loading capacity values for each DO impaired segment (Tables 9 and 10 of this Decision Document). The calculated loading capacity value is the maximum amount of oxygen-demanding material (e.g., ammonia-N (NBOD), total phosphorus, CBOD, SOD, and other oxygen-demanding materials) that DO impaired segments can receive and still maintain compliance with the DO WQS.

Tables 9 and 10: The DO TMDLs for Thorn Creek Watershed are located at the end of this Decision Document

Tables 9 and 10 of the Decision Document presents IEPA's loading reduction estimates for the DO TMDLs. These loading reductions (i.e., the percent reduction row at the bottom of each TMDL table) were calculated from field sampling data collected in the TCW. IEPA explained that its load reduction estimates are likely more conservative since they are based on a limited water quality data set.

IEPA calculated a reserve capacity value (i.e., 10% of the loading capacity) for the dissolved oxygen TMDLs in the Thorn Creek Watershed (see Tables 9 and 10 of this Decision Document). IEPA explained that this reserve capacity was supposed to account for projected population growth in the watershed (Section 2.3.5.5 of the final TMDL document).

EPA supports the data analysis and modeling approach utilized by IEPA in its calculation of WLA, LA and MOS for the DO TMDLs for the TCW. Additionally, EPA concurs with the loading capacities calculated by the IEPA for the TCW DO TMDLs. EPA finds IEPA's approach for calculating the loading capacity for the TCW DO TMDLs to be reasonable and consistent with EPA guidance.

TCW phosphorus TMDL: IEPA used the U.S. Army Corps of Engineers (USACE) BATHTUB model to calculate the loading capacity for the Sauk Trail Lake (RHI) TP TMDL. The BATHTUB model was utilized to link observed phosphorus water quality conditions and estimated phosphorus loads to in-lake water quality estimates. IEPA has previously employed BATHTUB successfully in other lake TMDLs in Illinois. BATHTUB is a steady-state annual or seasonal model that predicts a lake's growing season (e.g., June 1 to September 30) average surface water quality. BATHTUB utilizes annual or seasonal time scales which are appropriate because watershed TP loads are normally impacted by seasonal conditions.

BATHTUB has built-in statistical calculations which account for data variability and provide a means for estimating confidence in model predictions. BATHTUB employs a mass-balance TP model that accounts for water and TP inputs from tributaries, direct watershed runoff, the atmosphere, and sources internal to the lake, and outputs through the lake outlet, water loss via evaporation, and TP sedimentation and retention in the lake sediments. BATHTUB provides flexibility to tailor model inputs to specific lake morphometry, watershed characteristics and watershed inputs. The BATHTUB model also allows IEPA to assess different impacts of changes in nutrient loading. BATHTUB allows the user the choice of several different mass-balance TP models for estimating loading capacity.

The loading capacity of the TP lake TMDLs were determined through the use of BATHTUB and the Canfield-Bachmann subroutine and then allocated to the WLA, LA, and MOS (Section 1 and Appendix E of the Decision Document). To simulate the load reductions needed to achieve the WQS, a series of model simulations were performed. Each simulation reduced the total amount of TP entering Sauk Trail Lake during the growing season and computed the anticipated water quality response within the lake. The goal of the modeling simulations was to identify the loading capacity appropriate (i.e., the maximum allowable load to the system) necessary to attain WQS.

The BATHTUB modeling efforts were used to calculate the loading capacity for Sauk Trail Lake. The loading capacity is the maximum phosphorus load which Sauk Trail Lake can receive over an annual period and still meet the TP nutrient water quality targets (Table 11 of this Decision Document). Loading capacities were determined using Canfield-Bachmann equations from BATHTUB. The model equations were originally developed from data taken from over 704 lakes. The model estimates in-lake phosphorus concentration by calculating net phosphorus loss (e.g., phosphorus sedimentation) from annual phosphorus loads as functions of inflows to the lake, lake depth, and hydraulic flushing rate. To estimate loading capacity, the model is rerun, each time reducing current loads to the lake until the model result shows that in-lake total phosphorus would meet the applicable water quality standards.

IEPA subdivided the loading capacity among the WLA, LA, and MOS components of the TMDL (Table 11 of this Decision Document). These calculations were based on the critical condition, the summer growing season, which is typically when the water quality in each lake is typically degraded and phosphorus loading inputs are the greatest.

Table 11: Total Phosphorus TMDL for Sauk Trail Lake (RHI) in the Thorn Creek Watershed

Loading Source	TP (lbs/day)
Sauk Trail Lake (RHI)	
Chicago Heights MS4 (ILR400174)	0.001
Monee MS4 (ILG870335)	0.212
Park Forest MS4 (ILR400421)	0.553
South Chicago Heights MS4 (ILR400449)	0.159
University Park MS4 (ILR400250)	1.290
Illinois DOT (ILR400493)	0.004
Cook County Hwy Dept MS4 (ILR400485)	0.012
Will County MS4 (ILR400272)	0.009
WLA TOTAL	2.240
Internal Load Contribution (via BATHTUB)	0.045
Watershed Load - External source contributions to RHI	0.990
LA TOTAL	1.035
MOS (10%)	0.365
Loading Capacity	3.640
<i>Existing Load</i>	9.810
Necessary Reduction	63%

EPA supports the data analysis and modeling approach utilized by IEPA in its calculation of WLA, LA and MOS for the Sauk Trail Lake TP TMDL. Additionally, EPA concurs with the loading capacities calculated by the IEPA in its Sauk Trail Lake TP TMDL. EPA finds IEPA’s approach for calculating the loading capacity for its Sauk Trail Lake TP TMDL to be reasonable and consistent with EPA guidance.

TCW zinc TMDL: IEPA developed a LDC to calculate a zinc TMDL for Thorn Creek (HBD-02). The same LDC development strategy was employed for the zinc TMDL as was used to calculate the bacteria and chloride LDC values. IEPA used flow measurements from USGS gage #05536275 on Thorn Creek near Thornton, IL and DAR calculations to calculate the flows which were used in the FDC and the LDC for the Thorn Creek (HBD-02) zinc TMDL. The FDC were transformed into LDC by multiplying individual flow values by the zinc TMDL target (93 µg/L) and then multiplying that value by a conversion factor.

A zinc TMDL was calculated (Table 12 of this Decision Document) by IEPA. The LA value was calculated after the determination of the WLA, and the MOS. Load allocations (e.g., non-MS4 urban stormwater runoff) was not split among individual nonpoint contributors. Instead, load allocations were combined together into one value to cover all nonpoint source contributions. Table 12 of this Decision Document reports ten values (i.e., the midpoints of the 10-percent flow regimes) on the loading capacity curve. However, it should be understood that the components of the TMDL equation could be illustrated for any point on the entire loading capacity curve.

The LDC method can be used to display collected chloride monitoring data and allows for the estimation of load reductions necessary for attainment of the WQS. Using this method, daily loads were developed based upon the flow in the water body. Loading capacities were determined for Thorn Creek (HBD-02) for multiple flow regimes. This allows the TMDL to be represented by an allowable daily load across all

flow conditions. Although there are numeric loads for each flow regime, the LDC is what is being approved for this TMDL.

Table 12: The zinc TMDL for Thorn Creek (HBD-02) of the TCW is located at the end of this Decision Document

Table 12 of the Decision Document presents IEPA's loading reduction estimates for the TCW zinc TMDL. These loading reductions (i.e., the percent reduction row at the bottom of each TMDL table) were calculated from field sampling data collected in the TCW. IEPA explained that its load reduction estimates are likely more conservative since they are based on a limited water quality data set.

EPA supports the data analysis and modeling approach utilized by IEPA in its calculation of WLA, LA and MOS for the zinc TMDL for Thorn Creek (HBD-02). Additionally, EPA concurs with the loading capacities calculated by the IEPA in its TCW zinc TMDL. EPA finds IEPA's approach for calculating the loading capacity for its TCW zinc TMDL to be reasonable and consistent with EPA guidance.

The EPA finds that the TMDL document submitted by IEPA satisfies the requirements of the third criterion.

4. Load Allocations (LA)

EPA regulations require that a TMDL include LAs, which identify the portion of the loading capacity attributed to existing and future nonpoint sources and to natural background. Load allocations may range from reasonably accurate estimates to gross allotments (40 C.F.R. §130.2(g)). Where possible, load allocations should be described separately for natural background and nonpoint sources.

Comment:

IEPA determined the LA calculations for each of the TMDLs based on the applicable WQS. IEPA recognized that LAs for each of the individual TMDLs addressed by the TCW TMDLs can be attributed to different nonpoint sources.

TCW bacteria TMDLs: The calculated LA values for the bacteria TMDLs are applicable across all flow conditions in the TCW (Table 7 of this Decision Document). IEPA identified several nonpoint sources which contribute bacteria loads to the surface waters of the TCW, including; non-regulated urban stormwater runoff, stormwater from agricultural areas, failing septic systems and wildlife (e.g., deer, geese, ducks, raccoons, turkeys and other animals). IEPA did not determine individual load allocation values for each of these potential nonpoint source considerations but aggregated the nonpoint sources into a categorical LA value.

TCW chloride TMDL: The calculated LA values for the chloride TMDL are applicable across all flow conditions. IEPA identified several nonpoint sources which contribute chloride nonpoint source loads to the surface waters in the TCW (Table 8 of this Decision Document). Load allocations were recognized as originating from many diverse nonpoint sources including; stormwater runoff from areas not covered under a MS4 permit, contributions from agricultural lands and discharges from septic systems. IEPA did

not determine individual load allocation values for each of these potential nonpoint source considerations but aggregated the nonpoint sources into one categorical LA value.

TCW Ammonia-N (NBOD)/TP/CBOD/SOD – dissolved oxygen TMDLs: The calculated LA values for the DO TMDLs are applicable across all flow conditions. IEPA identified several nonpoint sources which contribute oxygen demanding material (e.g., ammonia-N (NBOD), total phosphorus, CBOD, SOD) nonpoint source loads to the surface waters in the TCW (Tables 9 and 10 of this Decision Document). Load allocations were recognized as originating from many diverse nonpoint sources including; stormwater runoff from areas not covered under a MS4 permit, contributions from agricultural lands and discharges from septic systems. IEPA did not determine individual load allocation values for each of these potential nonpoint source considerations but aggregated the nonpoint sources into one categorical LA value.

TCW phosphorus TMDL: The calculated LA values for the total phosphorus TMDL are applicable across all flow conditions. IEPA identified several nonpoint sources which contribute total phosphorus nonpoint source loads to the surface waters in the TCW (Table 11 of this Decision Document). Load allocations were recognized as originating from many diverse nonpoint sources including; stormwater runoff from areas not covered under a MS4 permit, contributions from agricultural lands and discharges, internal loading, wetland and forest sources, discharges from septic systems and wildlife nutrient contributions. IEPA did not determine individual load allocation values for each of these potential nonpoint source considerations but aggregated the nonpoint sources into one categorical LA value.

TCW zinc TMDL: The calculated LA values for the zinc TMDL are applicable across all flow conditions. IEPA identified several nonpoint sources which contribute zinc nonpoint source loads to the surface waters in the TCW (Table 12 of this Decision Document). Load allocations were recognized as originating from many diverse nonpoint sources including; stormwater runoff from areas not covered under a MS4 permit and soil contributions of naturally occurring zinc via stormwater runoff. IEPA did not determine individual load allocation values for each of these potential nonpoint source considerations but aggregated the nonpoint sources into one categorical LA value.

EPA finds IEPA's approach for calculating the LA to be reasonable and consistent with EPA guidance.

The EPA finds that the TMDL document submitted by IEPA satisfies the requirements of the fourth criterion.

5. Wasteload Allocations (WLAs)

EPA regulations require that a TMDL include WLAs, which identify the portion of the loading capacity allocated to individual existing and future point source(s) (40 C.F.R. §130.2(h), 40 C.F.R. §130.2(i)). In some cases, WLAs may cover more than one discharger, e.g., if the source is contained within a general permit.

The individual WLAs may take the form of uniform percentage reductions or individual mass based limitations for dischargers where it can be shown that this solution meets WQSs and does not result in localized impairments. These individual WLAs may be adjusted during the NPDES permitting process.

If the WLAs are adjusted, the individual effluent limits for each permit issued to a discharger on the impaired water must be consistent with the assumptions and requirements of the adjusted WLAs in the TMDL. If the WLAs are not adjusted, effluent limits contained in the permit must be consistent with the individual WLAs specified in the TMDL. If a draft permit provides for a higher load for a discharger than the corresponding individual WLA in the TMDL, the State/Tribe must demonstrate that the total WLA in the TMDL will be achieved through reductions in the remaining individual WLAs and that localized impairments will not result. All permittees should be notified of any deviations from the initial individual WLAs contained in the TMDL. EPA does not require the establishment of a new TMDL to reflect these revised allocations as long as the total WLA, as expressed in the TMDL, remains the same or decreases, and there is no reallocation between the total WLA and the total LA.

Comment:

TCW bacteria TMDLs: IEPA identified six NPDES permitted facilities in the TCW (Table 3 of this Decision Document) which contribute bacteria loads to the TCW bacteria TMDLs (Table 7 of this Decision Document). IEPA used the facility's design maximum flow (DMF) value to calculate the bacteria WLAs for the high flow and moist flow regimes of the LDC and the facility's design average flow (DAF) to calculate the bacteria WLAs for the mid-range, dry and low flow regimes of the LDC (Section 2.3.1.4 and 2.3.1.5 of the final TMDL document). The DMF and the DAF values were multiplied by the fecal coliform target of 200 cfu/100 mL to set the WLA across all flow regimes of the LDC (Table 2-4 of the final TMDL document).

MS4 WLA calculations for individual segments were based on MS4 area(s) within the contributing watersheds to that segment. IEPA analyzed the proportion of the total MS4 area to the total watershed area and used this proportion to assign a portion of the loading capacity to individual MS4 communities. IEPA explained that the MS4 WLAs were only applied to the upper 50% of flow regimes in the LDCs for each segment (e.g., high flow regime, moist flow regime and mid-range flow regime of the LDC).

EPA finds IEPA's approach for calculating the WLA for the TCW bacteria TMDLs to be reasonable and consistent with EPA guidance.

TCW chloride TMDL: IEPA identified one facility, the Thorn Creek Basin Sanitary District STP (Table 3 of this Decision Document) which contributes chloride loading to the Thorn Creek (HBD-04) segment (Table 8 of this Decision Document). Similar to the WLAs calculated for the bacteria TMDLs, IEPA used the facility's DMF to calculate the chloride WLA for the high flow and moist flow regimes of the LDC and the facility's DAF to calculate chloride WLA for the mid-range, dry and low flow regimes of the LDC. The DMF and the DAF values were multiplied by the chloride target of 500 mg/L to set the WLA across all flow regimes of the LDC (Table 2-22 of the final TMDL document).

To calculate MS4 WLAs for the chloride TMDL, IEPA employed the same strategy it used to calculate the MS4 WLA calculations for the bacteria TMDLs. Namely, the approach to determine the proportional area of the total MS4 area to the total watershed area. The chloride MS4 WLAs were only applied to the upper 50% of flow regimes in the LDCs for each segment (e.g., high flow regime, moist flow regime and mid-range flow regime of the LDC).

EPA finds IEPA's approach for calculating the WLA for the TCW chloride TMDL to be reasonable and consistent with EPA guidance.

TCW Ammonia-N (NBOD)/TP/CBOD/SOD – dissolved oxygen TMDLs: IEPA identified two facilities, the Thorn Creek Basin Sanitary District STP and the Paradise Park Mobile Home Park (Table 3 of this Decision Document) which contribute oxygen demanding material (e.g., ammonia-N (NBOD)) loads to two impaired DO segments in the TCW (Tables 9 and 10 of this Decision Document). Those impaired DO segments are HBD-06, Thorn Creek and HBDA-01, North Creek. The Thorn Creek Basin Sanitary District STP and the Paradise Park MHP have permitted load limits for ammonia nitrogen (ammonia-N) that vary seasonally. The QUAL2K modeled focused on critical time periods when low DO was observed in streams, typically later in the summer months. IEPA explained that permit limits for facilities addressed in the TCW DO TMDLs varied seasonally and those values were used to estimate WLAs for the DO impaired segments (Section 2.3.5.4 of the final TMDL document, Table 2-30 of the final TMDL document and Tables 9 and 10 of this Decision Document).

To calculate MS4 WLAs for the DO TMDLs, IEPA employed the same strategy which it used to calculate the MS4 WLA calculations for the bacteria TMDLs. Namely, the approach to determine the proportional are of the total MS4 area to the total watershed area.

EPA finds IEPA's approach for calculating the WLA for the TCW DO TMDLs to be reasonable and consistent with EPA guidance.

TCW phosphorus TMDL: IEPA assigned eight MS4 communities (Table 4 of this Decision Document) a WLA for the Sauk Trail Lake phosphorus TMDL (Table 11 of this Decision Document). IEPA used the same MS4 calculation strategy (i.e., proportional are of the total MS4 area to the total watershed area) for the Sauk Trail Lake phosphorus TMDL which it had employed to calculate MS4 WLAs for the other parameters in this TMDL report.

EPA finds IEPA's approach for calculating the WLA for the TCW total phosphorus TMDL to be reasonable and consistent with EPA guidance.

TCW zinc TMDL: IEPA identified one facility, the Aqua Illinois – University Park WWTP (Table 3 of this Decision Document) that contributes zinc loading to the Thorn Creek (HBD-02) segment (Table 12 of this Decision Document). Similar to the WLAs calculated for the bacteria TMDLs, IEPA used the facility's DMF to calculate the zinc WLA for the high flow and moist flow regimes of the LDC and the facility's DAF to calculate zinc WLA for the mid-range, dry and low flow regimes of the LDC. The DMF and the DAF values were multiplied by the zinc target of 93 mg/L to set the WLA across all flow regimes of the LDC (Table 2-26 of the final TMDL document).

To calculate MS4 WLAs for the zinc TMDL, IEPA employed the same strategy which it used to calculate the MS4 WLA calculations for the bacteria TMDLs. Namely, the approach to determine the proportional are of the total MS4 area to the total watershed area. The zinc MS4 WLAs were only applied to the upper 50% of flow regimes in the LDCs for each segment (e.g., high flow regime, moist flow regime and mid-range flow regime of the LDC).

EPA finds IEPA's approach for calculating the WLA for the TCW zinc TMDL to be reasonable and consistent with EPA guidance.

The EPA finds that the TMDL document submitted by IEPA satisfies the requirements of the fifth criterion.

6. Margin of Safety (MOS)

The statute and regulations require that a TMDL include a margin of safety (MOS) to account for any lack of knowledge concerning the relationship between load and wasteload allocations and water quality (CWA §303(d)(1)(C), 40 C.F.R. §130.7(c)(1)). EPA's 1991 TMDL Guidance explains that the MOS may be implicit, i.e., incorporated into the TMDL through conservative assumptions in the analysis, or explicit, i.e., expressed in the TMDL as loadings set aside for the MOS. If the MOS is implicit, the conservative assumptions in the analysis that account for the MOS must be described. If the MOS is explicit, the loading set aside for the MOS must be identified.

Comment:

The final TMDL submittal outlines the determination of the Margin of Safety for the bacteria, chloride, dissolved oxygen, phosphorus and zinc TMDLs. TMDLs for all parameters in the TCW TMDLs, except bacteria, incorporated an explicit MOS set at 10% of the loading capacity. The bacteria TMDLs employed both an explicit and implicit MOS.

TCW bacteria TMDLs: The bacteria TMDLs incorporate an implicit MOS in the TMDL calculations (Table 7 of this Decision Document). The WLA is based upon the 200 cfu/100 mL as a 30-day geometric mean portion of the WQS to determine the daily load. This significantly overestimates the bacteria reductions needed to attain WQS in the TCW. IEPA did not use a rate of decay, or die-off rate of pathogen species, in the TMDL calculations or in the creation of load duration curve for fecal coliform which is a conservative approach that ultimately over estimates the concentration of fecal coliform in the waterbody. Bacteria have a limited capability of surviving outside their hosts, and normally a rate of decay would be incorporated into the TMDL development process. IEPA determined that it was more conservative to use the WQS (200 cfu/100 mL) and not to apply a rate of decay because applying the rate of decay would increase the assimilative capacity in the stream and potentially result in higher limits being authorized NPDES permits.

As stated in *EPA's Protocol for Developing Pathogen TMDLs* (EPA 841-R-00-002), many different factors affect the survival of pathogens, including the physical condition of the water. These factors include, but are not limited to sunlight, temperature, salinity, and nutrient deficiencies. These factors vary depending on the environmental condition/circumstances of the water, and therefore it would be difficult to assert that the rate of decay caused by any given combination of these environmental variables was sufficient to meet the WQS of 200 cfu/100 mL. Thus, it is more conservative to apply the State's WQS as the MOS, because this standard must be met at all times under all environmental conditions.

TCW chloride TMDL, Ammonia-N (NBOD)/TP/CBOD/SOD – dissolved oxygen TMDLs, phosphorus TMDL and zinc TMDL: For all but one ammonia-N TMDL for Thorn Creek (HBD-06) (see Table 10 of this Decision Document), IEPA employed an explicit MOS set at 10% of the loading capacity. The explicit MOS was applied by reserving 10% of the total loading capacity, and then allocating the remaining loads to point and nonpoint sources (Tables 8 to 12 of this Decision Document). For the ammonia-N TMDL for Thorn Creek (HBD-06), IEPA used an explicit MOS of 5%.

The use of the LDC approach minimized variability associated with the development of the TCW TMDLs because the calculation of the loading capacity was a function of flow multiplied by the target value. The MOS was set at 5% for Thorn Creek (HBD-06) and 10% for the remainder of the segments to account for uncertainty due to field sampling error, basing assumptions on water quality monitoring with low sample sizes, and imperfect water quality targets. A 5% -10% MOS was considered appropriate, because the target values used in this TMDL had a firm technical basis and the estimated flows are believed to be relatively accurate because they were calculated based on a USGS gage located within or just outside of the subwatershed with the impaired segments. In addition, the QUAL2K model results indicate generally good calibration/validation results, indicating the model appropriately simulates the waterbodies (Appendix C of the final TMDL document).

The margin of safety is appropriate because the use of the LDC provides an accurate account of existing stream conditions (calculated by multiplying daily flows by existing pollutant levels), and an accurate account of the stream's loading capacity (calculated by multiplying daily flows by the appropriate water quality target). In other words, there is a good fit between observed (existing) data and predicted data using the LDC approach, thus providing a relatively accurate determination of the TMDL reductions needed. IEPA accounts for any uncertainty in this method by incorporating the MOS.

For the total phosphorus TMDLs, IEPA also noted that an implicit MOS is included in the loadings. IEPA believes the default values used in the BATHTUB model are conservative, as they are based upon a wide range of lakes and reservoirs in the East and Midwest.

The EPA finds that the TMDL document submitted by IEPA contains an appropriate MOS satisfying the requirements of the sixth criterion.

7. Seasonal Variation

The statute and regulations require that a TMDL be established with consideration of seasonal variations. The TMDL must describe the method chosen for including seasonal variations. (CWA §303(d)(1)(C), 40 C.F.R. §130.7(c)(1)).

Comment:

IEPA properly accounted for seasonality for the bacteria, chloride, dissolved oxygen and zinc TMDLs by use of the LDC method (or the related loading capacity approach), which inherently accounts for seasonal variation by using daily flows over a multi-year period (e.g., Section 2.3.1.2 of the final TMDL document for the bacteria TMDLs). LDC process for TMDL development efforts accounted for seasonal variation by utilizing streamflows over a wide range of flow conditions. For many of the LDC-based TMDLs in the TCW, runoff is the main transport mechanism which delivers pollutant loading into surface water environments. LDC graphs can provide insight toward understanding under which flow regimes/conditions exceedances of the WQS or water quality targets are occurring, and whether or not there is any seasonal flow component to those flow conditions (i.e., spring melt, summer precipitation events during lower flow periods, etc.)

As an example, bacterial loads vary by season, typically reaching higher numbers in the dry summer months when low flows and bacterial growth rates contribute to their abundance, and reaching relatively

lower values in colder months when bacterial growth rates attenuate and loading events, driven by stormwater runoff events aren't as frequent. Bacterial WQS need to be met between May 1st to October 31st, regardless of the flow condition. The development of the LDCs utilized estimated flow data from the nearby USGS gages (Table 6 of the final TMDL document). Flow data from the USGS gages represent a variety of flow conditions occurring in the recreation season. LDCs incorporated this flow information which was deemed representative of differing flow conditions and seasonal variability observed during the recreation season.

IEPA properly accounted for seasonality in the phosphorus TMDLs by use of monthly average precipitation records over a multi-year period in the BATHTUB model (Sections 2.3.6.2 of the TMDL). EPA agrees that this properly accounts for seasonal variations.

The EPA finds that the TMDL document submitted by IEPA satisfies the requirements of the seventh criterion.

8. Reasonable Assurance

When a TMDL is developed for waters impaired by point sources only, the issuance of a NPDES permit(s) provides the reasonable assurance that the wasteload allocations contained in the TMDL will be achieved. This is because 40 C.F.R. 122.44(d)(1)(vii)(B) requires that effluent limits in permits be consistent with, “the assumptions and requirements of any available wasteload allocation” in an approved TMDL.

When a TMDL is developed for waters impaired by both point and nonpoint sources, and the WLA is based on an assumption that nonpoint source load reductions will occur, EPA’s 1991 TMDL Guidance states that the TMDL should provide reasonable assurances that nonpoint source control measures will achieve expected load reductions in order for the TMDL to be approvable. This information is necessary for EPA to determine that the TMDL, including the load and wasteload allocations, has been established at a level necessary to implement water quality standards.

EPA’s August 1997 TMDL Guidance also directs Regions to work with States to achieve TMDL load allocations in waters impaired only by nonpoint sources. However, EPA cannot disapprove a TMDL for nonpoint source-only impaired waters, which do not have a demonstration of reasonable assurance that LAs will be achieved, because such a showing is not required by current regulations.

Comment:

The TCW bacteria, chloride, dissolved oxygen, phosphorus and zinc TMDLs provide reasonable assurance that actions identified in the implementation section of the final TMDL (i.e., Section 3 of the final TMDL document), will be applied to attain the loading capacities and allocations calculated for the impaired reaches within the TCW. The recommendations made by IEPA will be successful at improving water quality if the appropriate local groups work to implement these recommendations. Those mitigation suggestions, which fall outside of regulatory authority, will require commitment from state agencies and local stakeholders to carry out the suggested actions.

IEPA outlines its reasonable assurance efforts in Section 3 of the final TMDL document. IEPA outlines management measures and programs which will be employed to attain the loading capacities and allocations calculated for the impaired reaches within the TCW. Section 3 of the final TMDL document includes components of a more formal Implementation Plan for the TCW.

In 2014, the Chicago Metropolitan Agency for Planning, with the help of a consultant, amended the Thorn Creek Watershed Based Plan. The Thorn Creek Ecosystem Partnership and Thorn Creek Restoration Coalition co-authored the original Thorn Creek Watershed Based Plan (WBP) in 2005. This watershed based plan was supported with CWA 319 funds. The original and amended WBPs include various partner agencies and groups which have been active at varying capacities in the TCW; Forest Preserve District of Will County, Forest Preserve District of Cook County, Land Conservancy of Will County, Illinois Department of Natural Resources, Thorn Creek Basin Sanitary District, Prairie State College, Governors State University, local Villages and towns and others potential partners. It is unclear if there is a central group in the Thorn Creek Watershed area which is charged with leading the different agencies and local groups which in the past have engaged in efforts to improve overall surface water quality in the TCW. IEPA recommends that a watershed group be formed with local stakeholders as the main drivers of implementation decision making.

Reasonable assurance that the WLA set forth in the TMDL will be implemented is provided by regulatory actions. According to 40 CFR 122.44(d)(1)(vii)(B), NPDES permit effluent limits must be consistent with assumptions and requirements of all WLAs in approved TMDLs. IEPA's NPDES permit program is one of the implementing programs for ensuring WLA are consistent with the TMDL. Current NPDES permits will remain in effect until the permits are reissued.

Section 3 of the TMDL discusses various BMPs that, when implemented, will significantly reduce bacteria, chloride, oxygen demanding material, phosphorus and zinc inputs to surface waters of the TCW. In Table 3-8 of Section 3.14 of the final TMDL document, IEPA lists site-specific BMP costs, the programming which typically provide financial assistance for these BMPs (e.g., USDA-NRCS - Conservation Reserve Program (CRP), USDA- NRCS-Environmental Quality Incentives Program (EQIP), IDA-Conservation Practices Program (CPP)) and potential sponsors. In the amended WBP of 2014, most projects involved the incorporation of urbanized BMPs to the TCW. These BMPs included; green infrastructure projects, urban filter strips, brush management and streambank restoration efforts, culvert resizing, floodplain management and reconnection, wetland restoration, dam removal and vegetated swales.

Table 3-9 of the TMDL provides an estimated implementation schedule of actions and activities in the watershed that can reduce bacteria, chloride, oxygen demanding material, phosphorus and zinc loads into water bodies in the TCW. These actions address immediate (1-2 years), mid-term (5-10 years) and long-term (continuous) timeframes.

IEPA has also developed Load Reduction Strategies (LRS) for various pollutants in the watershed. These LRSs address impairments where numeric criteria have not been developed (e.g., total suspended solids (TSS), sedimentation/siltation). Although these are not TMDLs, the LRSs discuss sources and reductions needed for the various pollutants which impact overall water quality in the TCW. IEPA has concluded that reducing these pollutants will improve water quality in TCW and assist in implementing BMPs in the watershed.

The EPA finds that this criterion has been adequately addressed.

9. Monitoring Plan to Track TMDL Effectiveness

EPA's 1991 document, *Guidance for Water Quality-Based Decisions: The TMDL Process* (EPA 440/4-91-001), recommends a monitoring plan to track the effectiveness of a TMDL, particularly when a TMDL involves both point and nonpoint sources, and the WLA is based on an assumption that nonpoint source load reductions will occur. Such a TMDL should provide assurances that nonpoint source controls will achieve expected load reductions and, such TMDL should include a monitoring plan that describes the additional data to be collected to determine if the load reductions provided for in the TMDL are occurring and leading to attainment of water quality standards.

Comment:

The final TMDL document contains discussion on future monitoring within the TCW and milestones (Section 3.15 of the final TMDL document). Continued water quality monitoring within the basin is supported by IEPA. Additional water quality monitoring results could provide insight into the success or failure of BMP systems designed to reduce bacteria, chloride, oxygen demanding material, phosphorus and zinc loading into the surface waters of the watershed. Local watershed managers would be able to reflect on the progress of the various pollutant removal strategies and would have the opportunity to change course if observed progress is unsatisfactory.

Progress of TMDL implementation will be measured through monitoring efforts focused on:

- Tracking implementation of BMPs in the watershed;
- Estimating the effectiveness of BMPs;
- Additional monitoring of point source discharges in the watershed;
- Continued monitoring of impaired stream segments and tributaries;
- Monitoring storm-based high flow events; and
- Low flow monitoring in impaired stream segments.

IEPA anticipates continuing to measure water quality in the TCW via its Intensive Basin Survey water quality monitoring which occurs every 5 years. Additionally, IEPA explained that select ambient water quality locations are sampled nine times a year. Continuation of these programs will enable IEPA to evaluate water quality improvements in the TCW over time.

Water quality monitoring is a critical component of the adaptive management strategy employed as part of the implementation efforts utilized in the TCW. Water quality information will aid watershed managers in understanding how BMP pollutant removal efforts are impacting water quality. Water quality monitoring combined with an annual review of BMP efficiency will provide information on the success or failure of BMP systems designed to reduce pollutant loading into water bodies of the TCW. Watershed managers will have the opportunity to reflect on the progress or lack of progress and will have the opportunity to change course if progress is unsatisfactory.

The EPA finds that this criterion has been adequately addressed.

10. Implementation

EPA policy encourages Regions to work in partnership with States/Tribes to achieve nonpoint source load allocations established for 303(d)-listed waters impaired by nonpoint sources. Regions may assist States/Tribes in developing implementation plans that include reasonable assurances that nonpoint source LAs established in TMDLs for waters impaired solely or primarily by nonpoint sources will in fact be achieved. In addition, EPA policy recognizes that other relevant watershed management processes may be used in the TMDL process. EPA is not required to and does not approve TMDL implementation plans.

Comment:

The findings from the TCW TMDLs will be used to inform the selection of implementation activities in the watershed. The TMDL outlined some implementation strategies in Section 3 of the final TMDL document. IEPA outlined the importance of prioritizing areas within the TCW, education and outreach efforts with local partners, and partnering with local stakeholders to improve water quality within the watershed. The reduction goals for the bacteria, chloride, dissolved oxygen, phosphorus and zinc TMDLs may be met via a combination of the following strategies:

TCW bacteria TMDLs: The potential BMPs which, if installed and maintained, would likely result in decreases of bacteria in surface waters of the TCW are:

- ***Stormwater volume control and infiltration BMPs:*** To mitigate the impact of stormwater in the TCW, IEPA recommends the installation of stormwater BMPs, including some combination of; rain gardens, vegetated swales/bioswales/bioretenion areas, detention ponds, rain barrels, pervious pavement and infiltration trenches. Reducing peak flow stormwater inputs within the TCW may be accomplished via reducing impervious cover or employing other low impact development/ green technologies which allow stormwater to infiltrate, evaporate or evapotranspire before reaching the stormwater conveyance system.
- ***Filter strips/riparia area management practices:*** Protection of streambanks within the watershed through planting of vegetated/buffer areas with grasses, legumes, shrubs or trees will mitigate bacteria inputs into surface waters. These areas will filter stormwater runoff before the runoff enters into the surface waters of the TCW.
- ***Private septic system inspection and maintenance program*** - Septic systems are believed to be a source of bacteria to waters in the TCW. Failing systems are expected to be identified and addressed via upgrades to those septic systems not meeting local health ordinances. Septic system improvement priority should be given to those failing systems adjacent to surface waters (i.e., streams or lakes).
- ***Pasture management and fencing*** - Reducing livestock access to stream environments will lower the opportunity for direct transport of bacteria to surface waters. The installation of exclusion fencing near stream and river environments to prevent direct access for livestock, installing alternative water supplies, and installing stream crossings between pastures, would work to reduce the influxes of bacteria and improve water quality within the watershed. Additionally, introducing rotational grazing to increase grass coverage in pastures, and maintaining appropriate numbers of livestock per acre for grazing, can also aid in the reduction of bacteria inputs.

TCW chloride TMDL: The potential BMPs which, if installed and maintained, would likely result in decreases in chloride to surface waters of the TCW are:

- ***More efficient use of salt resources:*** Improving winter maintenance practices (i.e., reducing the amount of salt used) of municipal and private applicators for smarter and more efficient use of salt resources. The key challenge in reducing salt usage is balancing the need for public safety with the growing expectation for clear, dry roads, parking lots, and sidewalks through the variety of winter precipitation conditions in the TCW.

TCW Ammonia-N (NBOD)/TP/CBOD/SOD – dissolved oxygen and phosphorus TMDLs: The potential BMPs which, if installed and maintained, would likely result in decreases in oxygen demanding materials and phosphorus to surface waters of the TCW are:

- ***Filter strips, riparian buffers, bank stabilization and erosion control*** – Protection of streambanks within the watershed through planting of vegetated/buffer areas with grasses, legumes, shrubs or trees will mitigate bacteria inputs into surface waters. These areas will filter stormwater runoff before the runoff enters the main stem or tributaries of the TCW. An assessment of stream channel, river channel, and lakeshore erosional areas should be completed to evaluate areas where erosion control strategies could be implemented in the TCW. Implementation actions (e.g., planting deep-rooted vegetation near water bodies to stabilize streambanks) could be prioritized to target areas which are actively eroding. This strategy could prevent additional sediment inputs into surface waters of the TCW and minimize or eliminate degradation of habitat.
- ***Urban/Residential Nutrient Reduction Strategies:*** These strategies involve reducing stormwater runoff from lakeshore homes and other residences within the TCW. These practices would include; rain gardens, lawn fertilizer reduction, lake shore buffer strips, vegetation management and replacement of failing septic systems. Municipal programs, such as street sweeping, can also aid in the reduction of nutrients to surface water bodies within the TCW. Municipal partners can team with local watershed groups or water district partners to assess how best to utilize their monetary resources for installing new stormwater BMPs (e.g., vegetated swales) or retrofitting existing stormwater BMPs.
- ***Nutrient management*** – These strategies involve reducing nutrient transport from fields and minimizing soil loss. Specific practices would include; erosion control through conservation tillage, reduction of winter spreading of fertilizers, elimination of fertilizer spreading near open inlets and sensitive areas, installation of stream and lake shore buffer strips, streambank stabilization practices (gully stabilization and installation of fencing near streams), and nutrient management planning.
- ***Phosphorus-based lawn fertilizer restrictions*** – Runoff from urban and suburban areas may include phosphorus-based fertilizers. Reducing stormwater input from residential lawns, golf courses and other urban/suburban surfaces will reduce the phosphorus inputs to surface waters. Some of these practices could include; rain gardens, municipal street sweeping efforts, lake shore buffer strips, vegetation management and water quality educational programs which aim to inform the general public on nutrient reduction efforts and their impact on water quality.
- ***Private septic system inspection and maintenance program*** - Septic systems are believed to be a source of nutrients to waters in the TCW. Failing systems are expected to be identified and addressed via upgrades to those septic systems not meeting local health ordinances. Septic system improvement priority should be given to those failing systems adjacent to surface waters (i.e., streams or lakes).

- ***In-lake phosphorus loading (internal loading)*** - Internal nutrient loads may be addressed to meet the TMDL allocations outlined in the TCW phosphorus TMDLs.
 - *Hypolimnetic aeration*: Increasing oxygen at selected depths in a lake may enhance oxygen transfer efficiencies and reduce internal loading from phosphorus laden lake bottom sediments.
 - *Phosphorus inactivation from aluminum addition (i.e., aluminum sulfate or alum)*: The addition of chemical reactants (e.g., aluminum sulfate) to lakes of the TCW in order for those reactants to permanently bind phosphorus into the lake bottom sediments. This effort could decrease phosphorus releases from sediment into the lake water column during anoxic conditions.
 - *Dredging of lake bottom sediments*: IEPA explained that phosphorus release from lake bottom sediments is greatest from the recently deposited phosphorus rich layers of lake sediments. Removing this material, via dredging efforts, will contribute to reductions in internal loading.

TCW zinc TMDL: The potential BMPs which, if installed and maintained, would likely result in decreases in zinc to surface waters of the TCW are:

- ***Aerobic wetland*** – A large surface area pond with surface flows designed to precipitate metals out of the water column through oxidation reactions.
- ***Compost or anaerobic wetland*** – A large pond with surface flows designed to filter water through organic substrates (e.g., mushroom compost, peat moss, wood chips, sawdust or hay). Dissolved metals would absorb to the surfaces of the compost materials.
- ***Open limestone channels*** – Increasing the alkalinity of the waters and encouraging the precipitation of the dissolved metals via limestone amendments. This can be accomplished via an open drainage ditch of limestone or the placement of crushed limestone directly into a contaminated stream.
- ***Diversion wells*** – Another method to encourage the precipitation of dissolved metals by increasing the alkalinity from limestone amendments. The wells encourage the mixing of crushed limestone substrate with the metals in solution.
- ***Anoxic limestone drains*** – This is typically a pre-treatment step prior to the use of a constructed aerobic wetland. This involves passing metals contaminated water through a buried bed of limestone in order to precipitate the dissolved metals from solution. The key component of this treatment system is to minimize the contact with atmospheric oxygen which may reduce the utility of the limestone substrate.
- ***Vertical flow reactors*** – Consists of a treatment cell with an under-drained limestone base, topped with organic materials. The contaminated water flows through the compost and limestone and increases alkalinity via limestone dissolution and bacterial sulfate reductions.
- ***Active chemical treatments*** – The addition of chemicals (e.g., calcium carbonate, sodium hydroxide, sodium bicarbonate and anhydrous ammonia) to create a reaction to decrease the solubility of metals in solution and precipitate the metals out of solution into metal salt species which then settle out of solution. The main drawbacks of active chemical treatment systems are the costs, the operations and maintenance and the disposal of the precipitated metal sludge.

Education and Outreach Efforts - Increased education and outreach efforts to the general public bring greater awareness to the issues surrounding bacteria, chloride, oxygen demanding materials, phosphorus

and zinc contamination and strategies for reducing loading and transport of these pollutants should be prioritized as part of the overall implementation strategy.

The EPA finds that this criterion has been adequately addressed. The EPA reviews but does not approve implementation plans.

11. Public Participation

EPA policy is that there should be full and meaningful public participation in the TMDL development process. The TMDL regulations require that each State/Tribe must subject calculations to establish TMDLs to public review consistent with its own continuing planning process (40 C.F.R. §130.7(c)(1)(ii)). In guidance, EPA has explained that final TMDLs submitted to EPA for review and approval should describe the State's/Tribe's public participation process, including a summary of significant comments and the State's/Tribe's responses to those comments. When EPA establishes a TMDL, EPA regulations require EPA to publish a notice seeking public comment (40 C.F.R. §130.7(d)(2)).

Provision of inadequate public participation may be a basis for disapproving a TMDL. If EPA determines that a State/Tribe has not provided adequate public participation, EPA may defer its approval action until adequate public participation has been provided for, either by the State/Tribe or by EPA.

Comment:

The public participation section of the TMDL submittal is found in Section 4 of the final TMDL document. Throughout the development of the TCW TMDLs the public was given various opportunities to participate. IEPA and its TMDL contractor held a series of public meetings in the TCW during TMDL development, where IEPA described the watershed plan and TMDL process. The public comment period for the draft TMDL opened on October 11, 2018 and closed on November 11, 2018. IEPA posted the draft TMDL online at (<https://www2.illinois.gov/epa/Documents/iepa/water-quality/watershed-management/tmdls/reports/thorn-creek-watershed/draft-stage-3-report.pdf>) for the public comment period.

IEPA received four public comments during the public comment period. IEPA developed a response summary to address the comments submitted. EPA reviewed the comments and responses and has determined that IEPA responded appropriately to the comments. IEPA submitted all comments received during the public notice period and its response summary with the final TMDL submittal packet received by the EPA on December 16, 2020.

The EPA finds that the TMDL document submitted by IEPA satisfies the requirements of this eleventh element.

12. Submittal Letter

A submittal letter should be included with the TMDL submittal, and should specify whether the TMDL is being submitted for a *technical review* or *final review and approval*. Each final TMDL submitted to

EPA should be accompanied by a submittal letter that explicitly states that the submittal is a final TMDL submitted under Section 303(d) of the Clean Water Act for EPA review and approval. This clearly establishes the State's/Tribe's intent to submit, and EPA's duty to review, the TMDL under the statute. The submittal letter, whether for technical review or final review and approval, should contain such identifying information as the name and location of the water body, and the pollutant(s) of concern.

Comment:

The EPA received the final Thorn Creek watershed TMDL document, submittal letter and accompanying documentation from IEPA on December 16, 2020. The submittal letter explicitly stated that the final TMDLs referenced in Table 1 of this Decision Document were being submitted to EPA pursuant to Section 303(d) of the Clean Water Act for EPA review and approval. The submittal letter also included the name and location of the water bodies and the causes/pollutants of concern. This TMDL was submitted per the requirements under Section 303(d) of the Clean Water Act and 40 CFR 130.

The EPA finds that the TMDL transmittal letter submitted for the Thorn Creek watershed TMDLs by IEPA satisfies the requirements of this twelfth element.

13. Conclusion

After a full and complete review, the EPA finds that the 8 bacteria TMDLs, the 1 chloride TMDL, the 6 dissolved oxygen TMDLs, the 1 total phosphorus TMDL and the 1 zinc TMDL satisfy all elements for approvable TMDLs. This TMDL approval is for **seventeen (17) TMDLs**, addressing segments for primary contact recreation, aquatic life and aesthetic quality use impairments (Table 1 of this Decision Document).

The EPA's approval of these TMDLs extends to the water bodies which are identified above with the exception of any portions of the water bodies that are within Indian Country, as defined in 18 U.S.C. Section 1151. The EPA is taking no action to approve or disapprove TMDLs for those waters at this time. The EPA, or eligible Indian Tribes, as appropriate, will retain responsibilities under the CWA Section 303(d) for those waters.

¹ = Allocations approved by EPA, see Section 1 (pp. 4-5) of this Decision Document for further discussion

² = Instream numeric water quality standard does not exist for this parameter, therefore, an explicit WLA was not assigned for this parameter

³ = WLA is attributed to permitted point source (Thorn Creek Basin Sanitary District STP (IL0027723)), additional WLA capacity not available for MS4 allocations

⁴ = The WLA + MOS + RC exceeds the Loading Capacity, due to the proportion of loading attributed to the Thorn Creek Basin Sanitary District STP (IL0027723). No available load remains for the LA under these loading parameters.

Table of Contents

Executive Summary	xi
--------------------------------	-----------

Section 1 Methodology Development for the Thorn Creek Watershed

1.1	Total Maximum Daily Load Overview.....	1-1
1.2	TMDL Goals and Objectives for the Thorn Creek Watershed	1-2
1.3	Existing Data Inventory.....	1-5
1.3.1	Existing Water Quality Data	1-6
1.4	Methodology Overview	1-7
1.4.1	QUAL2K Overview	1-8
1.4.2	Load-Duration Curve Overview.....	1-9
1.4.3	BATHTUB Overview.....	1-9
1.4.4	LRS Overview for TSS and Sedimentation/Siltation in Sauk Trail Lake.....	1-10
1.5	Methodology Development	1-10
1.5.1	QUAL2K Model Development	1-10
1.5.1.1	QUAL2K Inputs.....	1-11
1.5.1.2	Stream Segmentation	1-11
1.5.1.3	Flow and Hydraulic Characteristics	1-12
1.5.1.4	Headwater Conditions	1-14
1.5.1.5	Diffuse Flow	1-14
1.5.1.6	Climate.....	1-14
1.5.1.7	Point Sources.....	1-14
1.5.1.8	QUAL2K Calibration.....	1-17
1.5.1.9	Sensitivity Analysis.....	1-17
1.5.2	Load-Duration Curves.....	1-17
1.5.2.1	Watershed Delineation and Flow Estimation	1-18
1.5.2.2	Fecal Coliform TMDLs for Streams.....	1-20
1.5.2.3	Chloride TMDLs for Streams	1-25
1.5.2.4	Zinc TMDLs for Streams	1-27
1.5.2.5	Silver TMDLs for Streams.....	1-28
1.5.2.6	TSS and Sedimentation/Siltation LRSs for Streams.....	1-29
1.5.3	BATHTUB Development for Sauk Trail Lake Impairments Caused by Total Phosphorus.....	1-31
1.5.3.1	Global Inputs	1-31
1.5.3.2	Reservoir Segment Inputs	1-32
1.5.3.3	Tributary Inputs	1-32
1.5.3.4	BATHTUB Confirmatory Analysis	1-34

Section 2 Total Maximum Daily Loads for the Thorn Creek Watershed

2.1	TMDL Endpoints for the Thorn Creek Watershed.....	2-1
2.2	Pollutant Sources and Linkages.....	2-3
2.3	TMDL Allocation.....	2-5
2.3.1	Fecal Coliform TMDL.....	2-5
2.3.1.1	Loading Capacity	2-5
2.3.1.2	Seasonal Variation	2-6

	2.3.1.3	Margin of Safety.....	2-6
	2.3.1.4	Waste Load Allocation.....	2-6
	2.3.1.5	Reserve Capacity.....	2-12
	2.3.1.6	Load Allocation and TMDL Summary	2-13
2.3.2		Chloride TMDL.....	2-18
	2.3.2.1	Loading Capacity.....	2-18
	2.3.2.2	Seasonal Variation.....	2-19
	2.3.2.3	Margin of Safety.....	2-19
	2.3.2.4	Waste Load Allocation.....	2-19
	2.3.2.5	Reserve Capacity.....	2-20
	2.3.2.6	Load Allocation and TMDL Summary	2-21
2.3.3		Zinc TMDL.....	2-22
	2.3.3.1	Loading Capacity.....	2-22
	2.3.3.2	Seasonal Variation.....	2-22
	2.3.3.3	Margin of Safety.....	2-22
	2.3.3.4	Waste Load Allocation.....	2-22
	2.3.3.5	Reserve Capacity.....	2-24
	2.3.3.6	Load Allocation and TMDL Summary	2-24
2.3.4		Silver TMDL	2-25
2.3.5		Dissolved Oxygen in Streams	2-25
	2.3.5.1	Loading Capacity.....	2-25
	2.3.5.2	Seasonal Variation.....	2-26
	2.3.5.3	Margin of Safety.....	2-26
	2.3.5.4	Waste Load Allocation.....	2-26
	2.3.5.5	Reserve Capacity.....	2-28
	2.3.5.6	Load Allocation and TMDL Summary	2-28
2.3.6		Total Phosphorus and DO TMDLs for Sauk Trail Lake	2-32
	2.3.6.1	Loading Capacity.....	2-32
	2.3.6.2	Margin of Safety.....	2-32
	2.3.6.3	Waste Load Allocation.....	2-32
	2.3.6.4	Reserve Capacity.....	2-33
	2.3.6.5	Load Allocation and TMDL Summary	2-33
2.4		LRS Allocation.....	2-34
	2.4.1	LRS for TSS and Sedimentation/Siltation in Stream Segments.....	2-34
		2.4.1.1 Target Loading Capacity.....	2-35
		2.4.1.2 Percent Reduction and LRS Summary for TSS and Sedimentation/Siltation in Streams.....	2-35
	2.4.2	LRS for TSS and Sedimentation/Siltation in Sauk Trail Lake.....	2-37

Section 3 Implementation Plan for the Thorn Creek Watershed

3.1	Implementation Overview	3-1
3.2	Adaptive Management	3-2
3.3	BMP Recommendations for Reducing TSS and Sedimentation/Siltation in Streams..	3-3
3.4	BMP Recommendations for Reducing TSS and Sedimentation/Siltation in Sauk Trail Lake.....	3-22
3.5	BMP Recommendations for Reducing Total Phosphorus and Increasing DO in Sauk Trail Lake.....	3-27
	3.5.1 Point Sources of Phosphorus.....	3-28

3.5.2	Nonpoint Sources of Phosphorus.....	3-28
3.6	BMP Recommendations for Reducing Total Phosphorus and Increasing DO in Streams	3-30
3.6.1	Point Sources of Nutrients and Oxygen-Demanding Materials.....	3-31
3.6.2	Stormwater Sources (both point and nonpoint) of Nutrients and Oxygen- Demanding Materials	3-32
3.7	BMP Recommendations for Reducing Fecal Coliform in Streams	3-36
3.7.1	NPDES Permitted Point Sources of Fecal Coliform.....	3-36
3.7.2	Nonpoint Sources of Fecal Coliform.....	3-37
3.8	BMP Recommendations for Reducing Chloride in Streams.....	3-39
3.8.1	Point Sources of Chloride	3-39
3.8.2	Nonpoint Sources of Chloride.....	3-40
3.9	BMP Recommendations for Reducing Silver and Zinc in Streams.....	3-42
3.9.1	Point Sources of Silver and Zinc	3-43
3.9.2	Nonpoint Sources of Silver and Zinc.....	3-43
3.10	Cost Estimates of BMPs	3-44

Executive Summary

A total maximum daily load, or TMDL, is a calculation of the maximum amount of a pollutant that a water body can receive and still meet water quality standards. Development of TMDLs for waters that do not support their designated uses is a requirement of Section 303(d) of the Clean Water Act (CWA). The Illinois EPA has a three-stage approach to TMDL development. The stages are:

Stage 1 – Watershed Characterization, Data Analysis, Methodology Selection

Stage 2 – Data Collection (optional)

Stage 3 – Model Calibration, TMDL Scenarios, Implementation Plan

TMDL development for this watershed began in 2008. Stage 1 was completed in March 2011 under a contract with AECOM (*Thorn Creek Watershed TMDL Stage 1 Report*, AECOM 2011). The stage 1 report is provided in **Appendix A**. No formal Stage 2 data collection was completed, but additional water quality data were collected and gathered by Illinois EPA and other agencies in the time between the completion of Stage 1 and the commencement of Stage 3. This TMDL Study encompasses 10 impaired waterbody segments within the Thorn Creek watershed. TMDL allocations have been set for phosphorus in Sauk Trail Lake as well as fecal coliform, zinc, chloride, and dissolved oxygen in stream segments. Additional impairment for silver in one stream segment is recommended for removal from the 303(d) list. Impairments for dissolved oxygen in Sauk Trail Lake are directly related to excess nutrients and addressed via the total phosphorus TMDL for that lake. Additional impairments in the watershed include total suspended solids and sedimentation/siltation. TMDLs are not provided for these impairments due to a lack of applicable numerical water quality standard; however, a load reduction target and implementation strategies for these parameters are discussed.

The sources of pollutants in the watershed include NPDES permitted facilities such as wastewater treatment facilities and regulated stormwater. In addition, sources of nonpoint pollution are largely the result of stormwater runoff in developed and undeveloped areas. Sources of pollutants in agricultural areas are primarily related to nutrient and sediment loading as a result of crop production.

The loading capacities for fecal coliform, chloride, zinc, and TSS/sedimentation in streams are determined using a load duration curve framework. The loading capacities for factors contributing to low dissolved oxygen impairments in streams are developed using QUAL2K models. The loading capacities for total phosphorus impairments in lakes are developed using a BATHTUB model. TMDLs and needed load reductions are presented in Section 2. The TMDL, or loading capacity, is distributed among permitted point sources as waste load allocations (WLA) and nonpoint and background sources as load allocations (LA). A margin of safety (MOS) is also included to account for uncertainty. Reserve Capacity (RC) may also be included in the TMDL load capacity (LC) analysis to account for future growth if the necessary information is available. The required pollutant reductions range from zero to >99%.

Section 3 of this report includes an implementation plan intended to provide basic information and direction to additional resources detailing potential implementation activities that can be employed to address the pollutant loads within the watershed.

Section 1

Methodology Development for the Thorn Creek Watershed

1.1 Total Maximum Daily Load Overview

A total maximum daily load, or TMDL, is a calculation of the maximum amount of a pollutant that a waterbody can receive and still meet water quality standards. TMDLs are a requirement of Section 303(d) of the Clean Water Act (CWA). To meet this requirement, the Illinois Environmental Protection Agency (Illinois EPA) must identify water bodies not meeting water quality standards and then establish TMDLs for restoration of water quality. Illinois EPA develops a list known as the "303(d) list" of water bodies not meeting water quality standards every two years, and it is included in the Integrated Water Quality Report. Water bodies on the 303(d) list are then targeted for TMDL development. The Illinois EPA's most recent Integrated Water Quality Report was submitted to the United States Environmental Protection Agency (USEPA) in July 2016. In accordance with USEPA's guidance, the report assigns all waters of the state to one of five categories. 303(d) listed water bodies make up category five in the integrated report (Appendix A of the Integrated Report).

In general, a TMDL is a quantitative assessment of water quality impairments, contributing sources, and pollutant reductions needed to attain water quality standards. The TMDL specifies the amount of pollutant or other stressor that needs to be reduced to meet water quality standards, allocates pollutant control or management responsibilities among sources in a watershed, and provides a scientific and policy basis for taking actions needed to restore a waterbody.

Water quality standards are laws or regulations that states authorize to enhance water quality and protect public health and welfare. Water quality standards provide the foundation for accomplishing two of the principal goals of the CWA. These goals are:

- Restore and maintain the chemical, physical, and biological integrity of the nation's waters
- Where attainable, to achieve water quality that promotes protection and propagation of fish, shellfish, and wildlife, and provides for recreation in and on the water

Water quality standards consist of three elements:

- The designated beneficial use or uses of a waterbody or segment of a waterbody
- The water quality criteria necessary to protect the use or uses of that particular waterbody
- An antidegradation policy

Examples of designated uses are primary contact (swimming), protection of aquatic life, and public and food processing water supply. Water quality criteria describe the quality of water that

will support a designated use. Water quality criteria can be expressed as numeric limits or as a narrative statement. Antidegradation policies are adopted so that water quality improvements are conserved, maintained, and protected.

1.2 TMDL Goals and Objectives for the Thorn Creek Watershed

The Illinois EPA has a three-stage approach to TMDL development. The stages are:

Stage 1 – Watershed Characterization, Data Analysis, Methodology Selection

Stage 2 – Data Collection (optional)

Stage 3 – Model Calibration, TMDL Scenarios, Implementation Plan

TMDL development for this watershed began in 2008. Stage 1 was updated in 2011 under a contract with AECOM (*Thorn Creek Watershed TMDL Stage 1 Report*, AECOM 2011). The Stage 1 Report is provided in Appendix A. Stage 2 data collection was recommended as a result of the Stage 1 reporting process, and additional water quality data were collected for a range of parameters at Sauk Trail Lake as part of the Stage 2 effort in 2008. Additional water quality data were collected and gathered by Illinois EPA, the Metropolitan Water Reclamation District of Greater Chicago (MWRD), and Thorn Creek Sanitary District (TCSD) during the time between the completion of Stage 1 and the commencement of Stage 3. All newly available data were assessed and incorporated into this Stage 3 report as appropriate.

The Thorn Creek watershed is comprised of 10-digit Hydrologic Unit Code (HUC-10) 0712000302, which includes four 12-digit subbasins (HUC-12): 071200030201 (Deer Creek), 071200030202 (Butterfield Creek), 071200030203 (North Creek), and 071200030204 (Thorn Creek). The following are the impaired waterbody segments in the Thorn Creek watershed:

- Thorn Creek (HBD-02)
- Thorn Creek (HBD-03)
- Thorn Creek (HBD-04)
- Thorn Creek (HBD-05)
- Thorn Creek (HBD-06)
- North Creek (HBDA-01)
- Butterfield Creek (HBDB-03)
- Deer Creek (HBDC)
- Deer Creek (HBDC-02)
- Sauk Trail Lake (RHI)

These impaired waterbody segments are shown on **Figure 1-1**. There are ten impaired waterbody segments within the watershed for which TMDL and/or a load reduction strategy (LRS) development was initiated in 2008. **Table 1-1** lists the waterbody segment and cause of impairment for the waterbody.

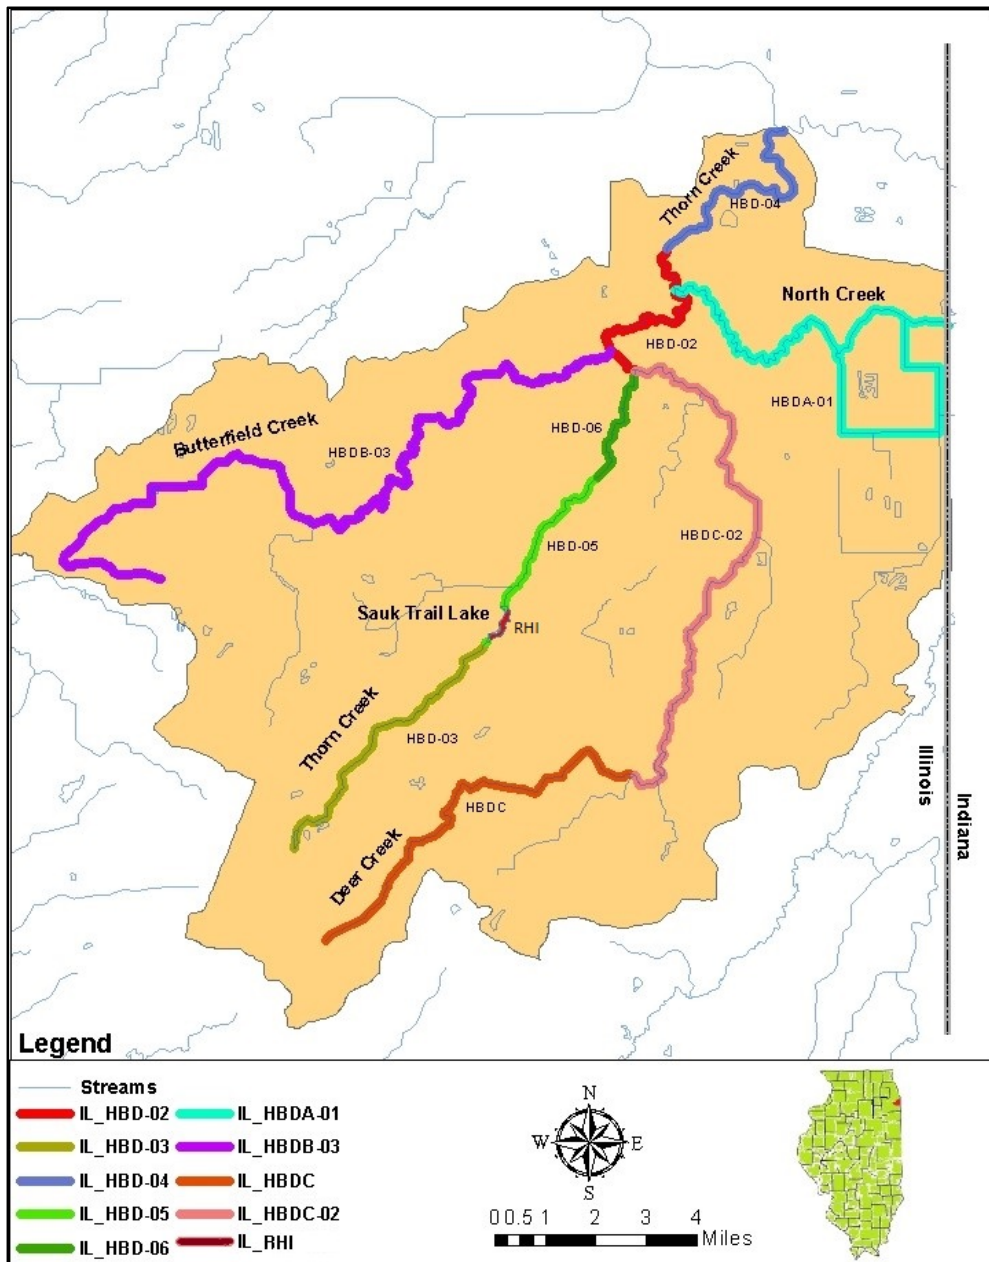

Figure 1-1: Impaired Waterbody Segments in Thorn Creek Watershed

Table 1-1: Waterbodies and Impairments Originally Targeted for TMDL and LRS Development in the Thorn Creek Watershed (based on the 2008 303(d) list)

Segment ID	Waterbody Name	TMDL Parameter	LRS Parameter
HBD-02	Thorn Creek	Dissolved Oxygen, Fecal Coliform, Silver, Zinc	TSS
HBD-03	Thorn Creek	Dissolved Oxygen, Fecal Coliform	
HBD-04	Thorn Creek	Dissolved Oxygen, Fecal Coliform, Chloride	
HBD-05	Thorn Creek	Fecal Coliform	
HBD-06	Thorn Creek	Dissolved Oxygen, Fecal Coliform, Chloride	
HBDA-01	North Creek	Dissolved Oxygen	Sedimentation/Siltation
HBDB-03	Butterfield Creek	Fecal Coliform	
HBDC	Deer Creek	Fecal Coliform	
HBDC-02	Deer Creek	Dissolved Oxygen, Fecal Coliform	Sedimentation/Siltation
RHI	Sauk Trail Lake	Phosphorus, Dissolved Oxygen ¹	Sedimentation/Siltation, TSS

¹ Dissolved oxygen impairment addressed through established linkage to total phosphorus impairment.

It should be noted that a small portion, less than 5%, of the Thorn Creek Watershed is in the state of Indiana. This area has no current impairments based on the Indiana 303(d) list or TMDLs developed for it. Load allocations are not assigned for locations outside of the state of Illinois in this TMDL report.

It should be noted that Sauk Trail Lake (RHI) is scheduled to have its dam removed in 2021-2022, by the US Army Corp of Engineers. Since the lake was created by damming Thorn Creek, removing the dam should effectively eliminate Sauk Trail Lake. The dam removal is expected to result in a host of positive environmental impacts, including ecosystem restoration and correcting habitat damage. When the dam is removed, the TMDL for Sauk Trail Lake will no longer be relevant.

The Stage 1 report was developed without investigating impairments caused by parameters without numeric water quality standards (sedimentation/siltation and TSS). Illinois EPA has previously only developed TMDLs for parameters that have numeric water quality standards while deferring development of TMDLs for parameters without numeric water quality standards until those criteria have been developed and adopted. As part of the TMDL development process, Illinois EPA started to include LRSs in TMDL watershed projects in 2012 for select pollutants that do not currently have numeric water quality standards.

For potential causes that do not have numeric water quality standards as noted in **Table 1-1**, TMDLs were not developed. However, LRSs (similar to TMDLs) were developed as part of Stage 3 based on target values established by Illinois EPA. In addition, some of these potential causes may

be addressed by implementation of controls for the pollutants with numeric water quality standards.

The TMDLs for the segments listed above specify the following elements:

- Loading Capacity (LC) or the maximum amount of pollutant loading a waterbody can receive without violating water quality standards
- Waste Load Allocation (WLA) or the portion of the TMDL allocated to existing or future point sources
- Load Allocation (LA) or the portion of the TMDL allocated to existing or future nonpoint sources and natural background
- Margin of Safety (MOS) or an accounting of uncertainty about the relationship between pollutant loads and receiving water quality
- Reserve Capacity (RC) or a portion of the load explicitly set aside to account for growth in the watershed, as necessary

These elements are combined into the following equation:

$$\text{TMDL} = \text{LC} = \Sigma\text{WLA} + \Sigma\text{LA} + \text{MOS} + \text{RC}$$

Developing an LRS involves determining the LC and load reduction that is needed in order for the waterbody to meet “Full Use Support” for its designated uses. In an LRS, the LC is not divided into WLA, LA, or MOS. These TMDL components are represented by one number as a target concentration for load reduction within each unique watershed. The LRS provides guidance (with no regulatory requirements) for voluntary nonpoint source reduction efforts by implementing agricultural and urban stormwater best management practices (BMPs).

TMDL and LRS development also takes into account the seasonal variability of pollutant loads so that water quality standards are met during all seasons of the year. Also, reasonable assurance that the TMDL and LRS targets will be achieved is described in the implementation plan. The implementation plan for the Thorn Creek watershed describes how water quality standards and targets will be met and attained. This implementation plan includes recommendations for implementing point source controls, urban and rural BMPs, cost estimates, institutional needs to implement BMPs and controls throughout the watershed, and a timeframe for completion of implementation activities.

1.3 Existing Data Inventory

Illinois EPA provided project files previously collected and analyzed by AECOM for the Thorn Creek watershed TMDL project completed under the previous consultant’s TMDL contract. This dataset included a large number of files containing both water quality data and general watershed data related to the TMDL development process. Versions of several of the water quality models proposed in the Stage 1 report for TMDL development were included in the data transfer. While this dataset provided much of the information necessary to complete Stage 3 of the TMDLs, some level of uncertainty existed as to the completeness and usability of each of the data sources. A review and assessment of the existing dataset was necessary, the results of which are discussed below.

1.3.1 Existing Water Quality Data

Water quality data provided by Illinois EPA included a number of MS Excel files containing water quality data originating from several sources. The bulk of the available water quality data were originally collected by Illinois EPA, MWRD, and TCSD. Based on a review of data summary and progress report documents produced by AECOM during the early stages of Stage 3 development, the original datasets compiled and used by AECOM did not appear to have been provided in full. Therefore, available data sources (Illinois EPA, MWRD, TCSD, etc.) were queried for relevant water quality data to supplement the existing water quality dataset provided.

All data identified were compiled into a watershed-specific database that contains approximately 15,000 sample results for the sampled waterbodies in the Thorn Creek watershed (**Appendix B**). The dataset includes sample results for approximately 70 different parameters, approximately 20 of which were potentially relevant to the TMDL and LRS development process (**Table 1-2**).

A summary of the relevant available data from the dataset compiled from Stage 1 data and additional data queried prior to the current Stage 3 development for each waterbody including period of record, sample count, minimum value, maximum value, and average value is provided in **Table 1-3**.

Table 1-2: List of Parameters Included in the Water Quality Dataset Compiled for the Thorn Creek Watershed

Alkalinity	Phosphorus, Dissolved
Chloride, Total	pH
Chlorophyll a	Silver, Dissolved
Coliform, Fecal	Silver, Total
Depth, Bottom	Solids, Fixed, Total
Depth, Secchi Disk	Solids, Fixed, Volatile
Hardness, Total	Solids, TSS
Nitrogen, Ammonia as NH3	Solids, Suspended, Volatile
Nitrogen, Nitrite (NO2) + Nitrate (NO3) as N	Zinc, Total
Oxygen, Dissolved	Zinc, Dissolved
Phosphorus, Total

¹ TMDL developed for primary contributing factors to low DO impairment as identified by QUAL2K modeling

² Insufficient data, current impairment not confirmed

1.4.1 QUAL2K Overview

The QUAL2K model was used to develop the dissolved oxygen (DO) TMDL for each of the DO-impaired stream segments in the Thorn Creek watershed (Thorn Creek HBD-02, HBD-03, HBD-04, HBD-06; North Creek HBDA-01; and Deer Creek HBDC-02). QUAL2K is a one-dimensional stream water quality model applicable to well-mixed streams. The model assumes steady state hydraulics and allows for point source inputs, diffuse loading and tributary flows. In general, QUAL2K incorporates historical water quality data, observed hydraulic information, and point source discharge data along with model defaults to predict the resulting instream DO concentrations (see **Schematic 1**).

Schematic 1

1.4.2 Load-Duration Curve Overview

LC analyses were performed for each of the stream segments in this watershed impaired by fecal coliform bacteria, silver, zinc, chloride, TSS, and sedimentation/siltation through the development of a series of load-duration curves. A load-duration curve is a graphical representation of the maximum load of a pollutant that a stream segment can assimilate over a range of flow scenarios while still meeting the instream water quality standard. The load-duration curve approach utilizes historical flow data and observed water quality data to assess the magnitude and frequency of exceedances as well as to determine the flow scenarios when exceedances occur most often (see **Schematic 2**). In the Thorn Creek watershed, load duration curves were constructed at segments Thorn Creek HBD-02, HBD-03, HBD-04, HBD-05, and HBD-06 and Butterfield Creek HBDB-03 and Deer Creek HBDC and HBDC-02 for fecal coliform; Thorn Creek HBD-02 for silver and zinc; Thorn Creek HBD-04 and HBD-06 for chloride; Thorn Creek HBD-02 for TSS; and North Creek HBDA-01 and Deer Creek HBDC-02 for sedimentation/siltation (NVSS).

Schematic 2

1.4.3 BATHTUB Overview

The BATHTUB model was used for phosphorus and DO assessments for Sauk Trail Lake. The BATHTUB model performs steady-state water and nutrient balance calculations in a spatially segmented hydraulic network that accounts for advective and diffusive transport, and nutrient sedimentation. The model relies on empirical relationships to predict lake trophic conditions and subsequent DO conditions as functions of total phosphorus and nitrogen loads, residence time, and mean depth (USEPA 1997). Oxygen conditions in the model are simulated as meta and hypolimnetic depletion rates, rather than explicit concentrations.

TMDL analysis for total phosphorus in Sauk Trail Lake involved the use of observed data coupled with the rational method as inputs to the BATHTUB models. This method required inputs from several sources including online databases and geographic information system (GIS)-compatible data.

Schematic 3

Schematic 3 shows the data inputs for the BATHTUB models that were used to calculate the TMDLs. Subbasin flows were estimated using the area ratio method and phosphorus loadings to each reservoir from the surrounding watersheds were estimated using the unit area load method, also known as the "export coefficient" method (USEPA 2001). This method is based on the assumption that, on an annual basis and normalized to area, a roughly constant runoff pollutant loading can be expected for a given land use type. This method also requires that unit area loads are not applied to watersheds that differ greatly in climate, hydrology, soils, or ecology from those from which the parameters were derived (USGS 1997).

Once the subbasin flows and concentrations were estimated, they were used as input for the BATHTUB models. The BATHTUB model uses empirical relationships between mean reservoir depth, total phosphorus inputted to the reservoir, and the hydraulic residence time to determine in-reservoir concentrations (see Schematic 3).

1.4.4 LRS Overview for TSS and Sedimentation/Siltation in Sauk Trail Lake

A simple spreadsheet approach was used to calculate the reduction in TSS loading into Sauk Trail Lake required to meet the watershed-specific target value established by Illinois EPA of 72.7 milligrams per liter (mg/L). LRS targets are based on data from all stream segments or lakes within the HUC-10 basins of the watershed, as well as stream segments or lakes which closely border the watershed in neighboring HUC-10 basins, in order to best represent the land use, hydrologic, and geologic conditions unique to the watershed. Load reduction targets were calculated by Illinois EPA using data from stream/lake segments whose most current assessment shows full support for aquatic life and data that has passed quality assurance and quality checks within Illinois EPA and are in accordance with state and federal laws.

The LRS calculations utilize the watershed flow estimates similar to those developed as part of the BATHTUB model, the relative proportion of the lake watershed made up by each subbasin, measured in-lake TSS concentrations, and the target value developed by Illinois EPA to calculate the current daily load of TSS into the lake (pounds [lbs]/day), the target load (lbs/day), and the percent reduction needed in order to meet the LRS target. This simplified approach is appropriate for LRS development as it does not require the explicit assessment of WLAs or LAs.

1.5 Methodology Development

The following sections further discuss and describe the methodologies utilized to examine fecal coliform, chloride, TSS, sedimentation/siltation, silver, zinc and DO levels in the stream segments of the Thorn Creek watershed, as well as total phosphorous, TSS, sedimentation/siltation and DO levels in Sauk Trail Lake.

1.5.1 QUAL2K Model Development

QUAL2K (Q2K) is a river and stream water quality model that is intended to represent a modernized version of the QUAL2E (Q2E) model (Brown and Barnwell 1987). The original Q2E model is well-known and USEPA-supported. The modernized version has been updated to use MS Excel as the user interface and has expanded the options for stream segmentation as well as a number of other model inputs. Q2K simulates DO dynamics as a function of nitrogenous oxygen demand (NBOD) and carbonaceous oxygen demand (CBOD), atmospheric reaeration, sediment oxygen demand (SOD), and plant photosynthesis and respiration. The model also simulates the fate and transport of nutrients and biochemical oxygen demand (BOD) and the growth and abundance of floating (phytoplankton) and attached (periphyton) algae (as chlorophyll-a). Stream hydrodynamics and temperature are important controlling parameters in the model. Headwater, point source, and non-point source loadings and flows are explicitly input by the user. The model simulates steady-state diurnal cycles. Model parameter default values are provided in the model based on past studies and are recommended in the absence of site-specific information. Along with its capability to aid in DO assessment, Q2K can also be used to model nutrient and pH fluctuations within a stream segment.

All of the stream segments in the Thorn Creek watershed that are impaired for DO adjoin, allowing for a single contiguous Q2K model to be developed capable of modeling all of the impaired segments simultaneously. Because Q2K models simulate steady-state diurnal cycles, the TMDL endpoints used for analysis at each segment were the 7-day average water quality standards of 6.0 mg/L (March-July) and the instantaneous minimum standard of 5.0 mg/L (March – July). The use of the 7-day average standard as a TMDL endpoint, in addition to the 5.0 mg/L (March-July) instantaneous minimum standards, serves as a conservative measure adding to the implicit MOS included in the final TMDL calculations for each impaired segment (see further discussion in **Section 2**).

1.5.1.1 QUAL2K Inputs

Table 1-5 contains the categories of data required for the Q2K models along with the sources of data used to analyze each of the impaired stream segments in the Thorn Creek watershed.

Table 1-5: Q2K Data Inputs

Input Category	Data Source
Stream Segmentation	GIS data
Hydraulic characteristics	Aerial photographs; GIS; Illinois EPA field data
Headwater conditions	Historic water quality data
Meteorological conditions	National Climatic Data Center
Point Source contributions	Illinois EPA, USEPA's Permit Compliance System and Integrated Compliance Information System

Empirical data amassed during Stage 1 of TMDL development were used to build the Q2K models.

1.5.1.2 Stream Segmentation

The Q2K model represents a river as a series of reaches. Each reach exhibits relatively consistent channel geometry and hydraulic characteristics. Each TMDL segment was represented by one or more Q2K model segments, each of which was further divided into many computational units.

The modeled Thorn Creek system includes one first order tributary (Thorn Creek), divided into seven reaches (including Sauk Trail Lake), and three tributaries. The tributary stream segments were divided into a total of eight reaches in the model: two reaches for North Creek, three reaches for Butterfield Creek, and three reaches for Deer Creek. A total of 54.2 river miles were included in the model: 6.6 miles of North Creek, 14.7 miles Butterfield Creek, 15.8 miles of Deer Creek, and 17.1 miles of the mainstem. **Figure 1-2** shows the stream segmentation used for the Thorn Creek Q2K model.

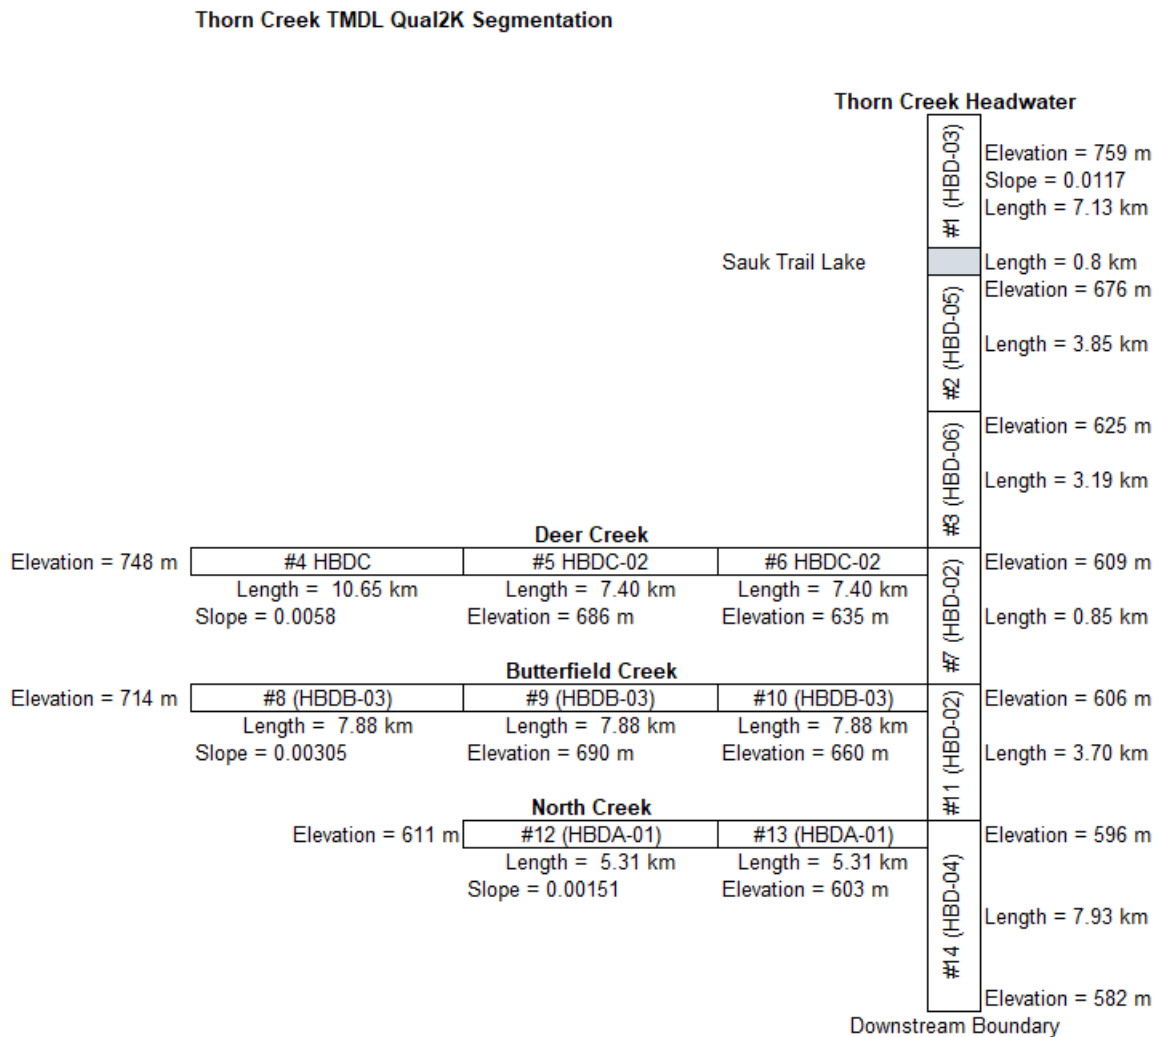

Figure 1-2: Stream Segmentation Used for the Thorn Creek Qual2K Model

1.5.1.3 Flow and Hydraulic Characteristics

Flow rates for the modeled period were set in the model based on measured flows at a series of U.S. Geological Survey (USGS) flow gauges distributed throughout the modeled basin. The following gauges were used to support the modeling (**Figure 1-3**): 05536215 (Thorn Creek at Glenwood), 05536235 (Deer Creek near Chicago Heights), 05536255 (Butterfield Creek at Flossmoor), 05536265 (Lansing Ditch near Lansing), and 05536275 (Thorn Creek at Thornton). The majority of stream hydraulic data specified in the model is based on physical stream characteristic data collected during an additional Illinois EPA field survey conducted in September 2007 under relatively low-flow conditions. The Sauk Trail Lake segment was parameterized based on available lake bathymetry data and GIS analysis.

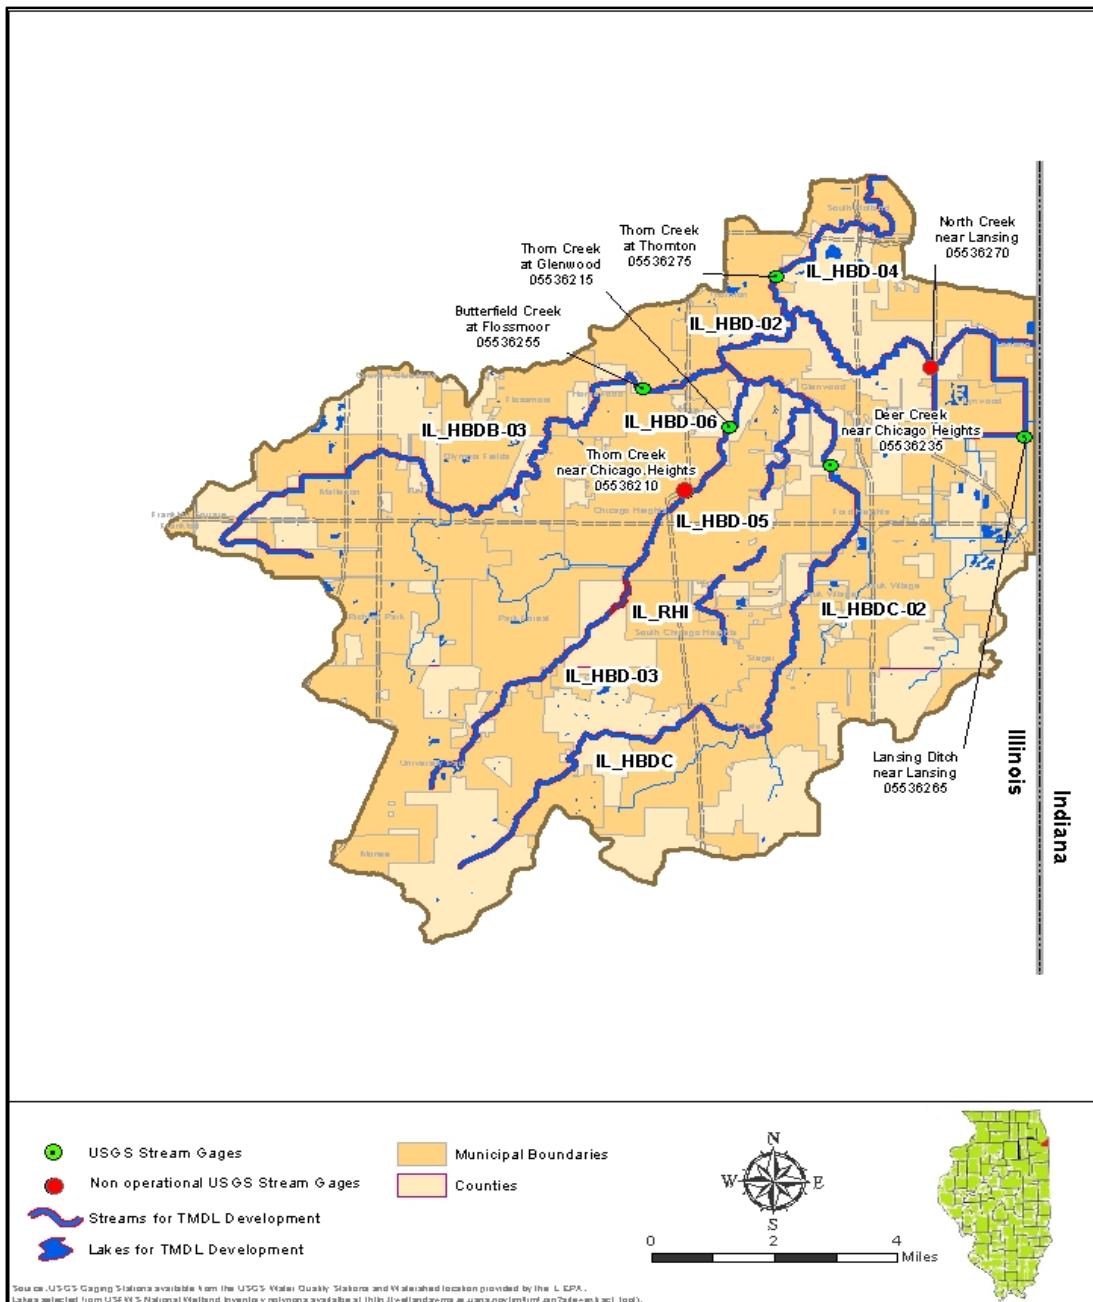

Figure 1-3: USGS Stream Gages in Thorn Creek Watershed

1.5.1.4 Headwater Conditions

Separate headwater conditions were established for each of the four upper reaches of the Thorn Creek watershed (Thorn Creek, Butterfield Creek, Deer Creek, and North Creek). Headwater water quality conditions were set based on available in-stream water quality data for July 6, 2005, as this represents the most recent date within the critical period for DO assessment (late in the growing season and under low flows) for which water quality data collected at multiple locations across the modeled system were available. Synoptic data collected on this date were also used for calibrating the model, discussed below. Headwater flows were estimated using area-weighting of available stream gauge data for July 6, 2005.

1.5.1.5 Diffuse Flow

Diffuse flow gains were assumed for the Thorn Creek reaches based on flow balance calculations that included USGS flow gauge and point source discharge (described below) information. As with the headwater flow calculations, area-weighting calculations were used to estimate flow gains, exclusive of point sources, at additional locations throughout the system. These flows were included in the model as diffuse inputs to the system.

1.5.1.6 Climate

Q2K requires inputs for climate, as they pertain to the calculation of water temperature and reaeration. Temperature and wind speed data for the synoptic sampling date were obtained from the National Climatic Data Center. Data from the nearest available weather stations (Lansing Municipal Airport and NOAA Weather Station IL116616 in Park Forest, IL) were used for the model.

1.5.1.7 Point Sources

Two major and three minor National Pollutant Discharge Elimination System (NPDES) permitted point source dischargers with reported discharges during the model simulation period were included in the model. Additional NPDES permitted discharges in the watershed, such as the Park Forest Excess Flow Facility (IL0047562) and several stormwater discharge permittees which only discharge under high flow conditions, do not discharge during the critical low flow period and were therefore not included in the critical condition model. However, intermittent discharges are a potential source of nutrients and oxygen demanding materials at times outside of the critical condition model considered in the TMDL and as such, strategies for load reductions for intermittent discharges are discussed in Section 3 of this report.

Q2K allows user input of point source locations, flow, and water quality data. Permit records were reviewed and reported discharge data were used for model input. Where necessary concentration data were not available, estimates based on other facilities in the watershed, and downstream measured concentrations, were used to develop approximated point source model inputs. **Table 1-6** contains final model input information for each facility, including average flow for each facility in million gallons per day (MGD). The locations of each facility are shown in **Figure 1-4**. Flow information was available for each discharger; however, permit limit concentration data are available only for parameters that are sampled per permit requirements.

Table 1-6: Point Source Discharge Model Inputs for Thorn Creek QUAL2K Models, DO and Oxygen Demanding Materials

Facility Name	Permit Number	Average Facility Flows (MGD)	Receiving Segment	DO Model Input (mg/L)	CBOD (mg of O ₂ /L)	Ammonia N (mg/L)

Chicago Heights Steel	IL0001678	0.013	Thorn Creek	7.0	23.0	

¹ Facility has a permitted DAF of 0.27 MGD but flow is reported as no-discharge during modeled period.

1.5.1.8 QUAL2K Calibration

Sufficient water quality data were available to perform an approximate calibration of the model kinetic and transport rates. A synoptic data set, spatially distributed data obtained on the same day, was available for a low flow period on July 6, 2005. This data set was used to calibrate key model kinetic parameters and reach hydraulics. This calibration day can be considered representative of critical conditions with respect to DO, as it was during a period of low flows and high temperatures. The river was effluent dominated during this low flow period. Measured DO levels for this day were consistently below the applicable water quality standards, further supporting this assumption of critical conditions. Of note, and relevant to the model calibration and TMDL calculations (Section 2), the lowest measured DO levels on this sampling day were upstream of all point source discharges.

The calibration process focused on those water quality constituents relevant to dissolved oxygen simulations for which measured data were available, including water temperature, CBOD, nitrate, ammonia, total phosphorus, and DO. The model was considered calibrated when relative consistency between modeled vs. measured profiles were achieved for all parameters, based on best professional judgement. All model kinetic parameters were maintained within the model recommended ranges during the calibration process (**Appendix C**) and most were maintained at model default values. Calibrated kinetic parameters are in close agreement with those calibrated for other reaches in this watershed (described above). Due to a lack of adequate reach hydraulic (cross-section) data for the sampling period, hydraulic parameters (mean velocities and depths) were also treated as calibration parameters. These parameters were varied from the initial values described above in order to achieve the reaeration rates implied by the data and ultimately replicate measured DO profiles. Finally, diffuse flow input concentrations of nutrients and carbonaceous biochemical oxygen demand, as implied by the synoptic data set, were set as part of the calibration process. Final measured vs. modeled calibration profiles, and simulated reaeration rates, are provided in **Appendix C**.

1.5.1.9 Sensitivity Analysis

A sensitivity analysis was conducted to determine the model parameters that DO calculations are most sensitive to. This analysis identified SOD rates and the selected reaeration model as the highest sensitivity parameters, with respect to modeled DO levels. Moderately sensitive parameters included bottom algae growth/respiration/excretion rates, CBOD oxidation rates, and nitrification rates. Geometric properties such as Manning's "n" were among the least sensitive parameters.

1.5.2 Load Duration Curves

Load duration curves are useful for assessing the range of pollutant loads allowable at various flow rates throughout the full flow regime of a stream. This approach was used to characterize the current loading of fecal coliform bacteria, silver, zinc, and TSS, to HBD-02 of Thorn Creek; fecal coliform to impaired segment HBD-03 of Thorn Creek; fecal coliform and chloride to impaired segment HBD-04 of Thorn Creek; fecal coliform to impaired segment HBD-05 of Thorn Creek; fecal coliform and chloride to impaired segment HBD-06 of Thorn Creek; fecal coliform to impaired segment HBDB-03 of Butterfield Creek; and fecal coliform to impaired segments HBDC and HBDC-02 of Deer Creek. Impairments caused by excessive sedimentation or siltation in

segments HBDA-01 of North Creek and HBDC-02 of Deer Creek were also assessed using NVSS as a surrogate analyte for the load duration curve methodology. NVSS was selected as a surrogate analyte by Illinois EPA during the development of the agency's LRS methodology.

1.5.2.1 Watershed Delineation and Flow Estimation

Watershed areas for each impaired stream segment were delineated with GIS analyses through use of the National Elevation Dataset, as well as through visual assessment of aerial photographs. The watershed delineations result in the following estimates of directly contributing watershed used for each impaired segment's load duration curve development:

- Thorn Creek HBD-02: 104 square miles
- Thorn Creek HBD-03: 8.8 square miles
- Thorn Creek HBD-04: 107 square miles
- Thorn Creek HBD-05: 17.8 square miles
- Thorn Creek HBD-06: 25.5 square miles
- North Creek HBDA-01: 22.4 square miles
- Butterfield Creek HBDB-03: 25.8 square miles
- Deer Creek HBDC: 7.8 square miles
- Deer Creek HBDC-02: 26.5 square miles

Figure 1-5 shows the location of the water quality stations on each segment as well as the boundary of the GIS-delineated watersheds.

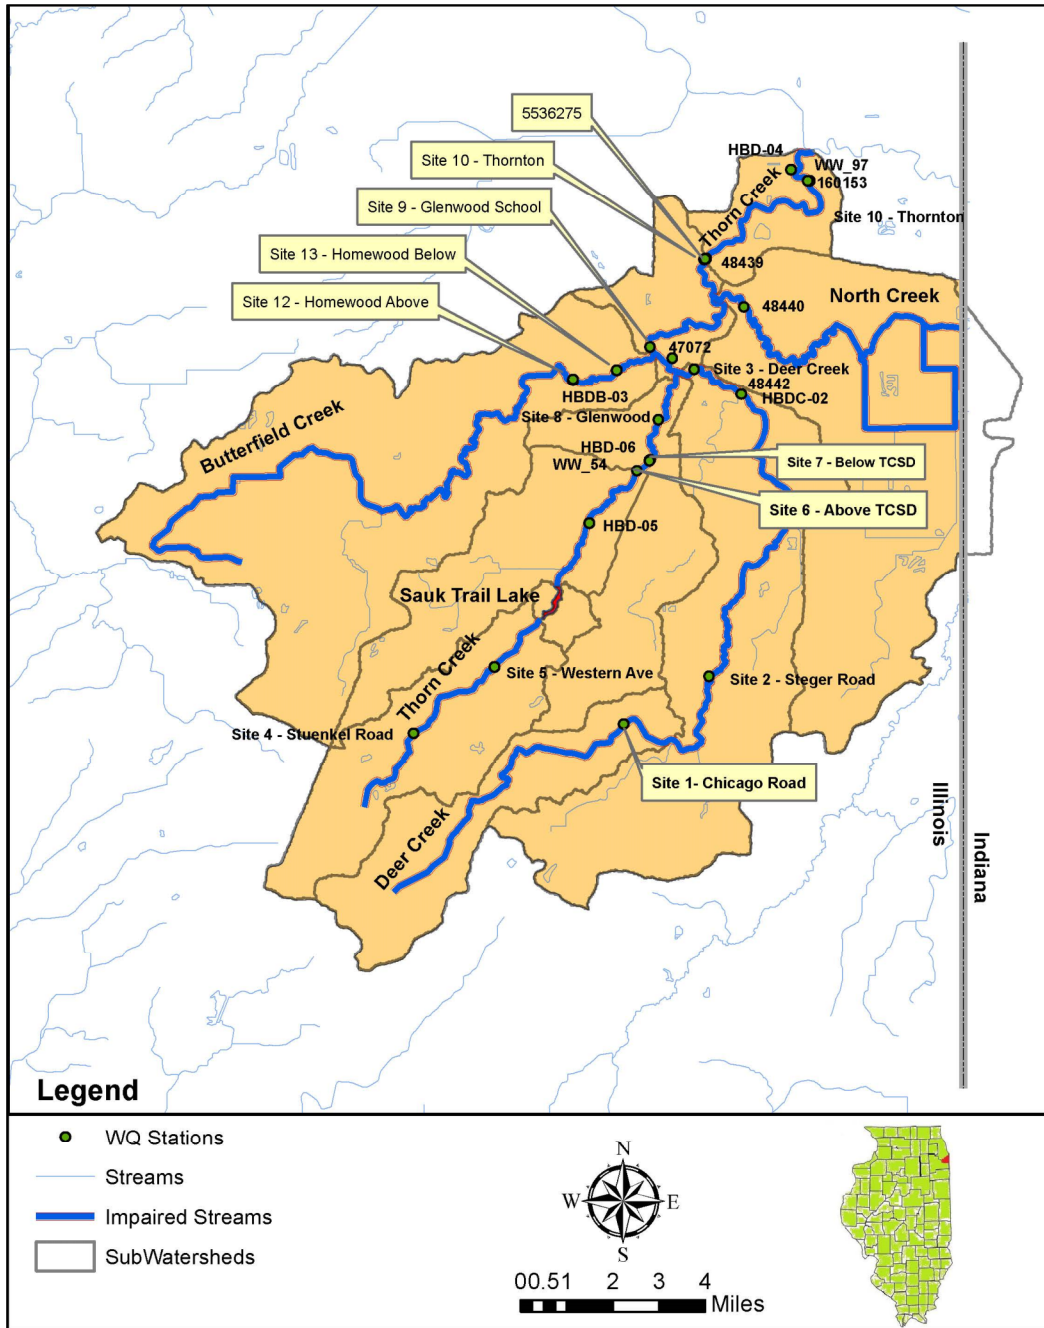

Figure 1-5: Water Quality Sampling Stations in the Thorn Creek Watershed

In order to create a load duration curve, it is necessary to obtain stream flow data that corresponds to each water quality sample. There are five active USGS stream gauges within the Thorn Creek watershed (see **Figure 1-3**). Where available, stream gauges located on an impaired segment were used to estimate flows. In other cases, the closest available gauge with similar watershed characteristics was used to estimate flows using the drainage area ratio method represented by the following equation:

$$Q_{\text{gauged}} \left(\frac{\text{Area}_{\text{ungauged}}}{\text{Area}_{\text{gauged}}} \right) = Q_{\text{ungauged}}$$

where, Q_{gauged} = Streamflow of the gauged basin
 Q_{ungauged} = Streamflow of the ungauged basin
 $\text{Area}_{\text{gauged}}$ = Area of the gauged basin
 $\text{Area}_{\text{ungauged}}$ = Area of the ungauged basin

The assumption behind the equation is that the flow per unit area is equivalent in watersheds with similar characteristics. Therefore, the flow per unit area in the gauged watershed multiplied by the ratio of the area of the ungauged watershed to the area of the gauged watershed estimates the flow for the ungauged watershed.

Data downloaded through the USGS for the surrogate gauges for the available periods of record were adjusted to account for point source influences in the watershed upstream of the gauging stations. Average daily flows from all NPDES permitted facilities upstream of the surrogate USGS gauges were subtracted from the gauged flow prior to flow-per unit-area calculations. The resulting estimates account for flows associated with precipitation and overland runoff only. Average daily flows from permitted NPDES discharges upstream of the impaired segments in the Thorn Creek watershed were then added back into the equation to more accurately reflect estimated daily streamflow conditions in a given segment. The gauge used to approximate flow for each impaired stream segment or waterbody are provided in **Table 1-7**. Spreadsheets used for the area ratio flow calculations are provided in **Appendix D**.

Table 1-7: Active USGS Gauges and Applicable Segments/Waterbodies in the Thorn Creek Watershed

Gauge ID	Gauge Name	Gauged Watershed Area (Sq. Miles)	Applicable Impaired Segments
USGS 05536215	Thorn Creek at Glenwood	24.7	Thorn Creek – HBD-03, HBD-05 and HBD-
USGS 05536235	Deer Creek near Chicago Heights	23.1	Deer Creek – HBDC and HBDC-02
USGS 05536255	Butterfield Creek at Flossmoor	23.5	Butterfield Creek – HBDB-03
USGS 05536265	Lansing Ditch near Lansing	8.8	North Creek – HBDA-01
USGS 05536275	Thorn Creek at Thornton	104	Thorn Creek – HBD-02 and HBD-04

1.5.2.2 Fecal Coliform TMDLs for Streams

Flow duration curves for fecal coliform were developed for impaired segments of Thorn Creek (HBD-02, HBD-03, HBD-04, HBD-05, and HBD-06), Butterfield Creek (HBDB-03), and Deer Creek (HBDC and HBDC-02) by determining the percent of days each estimated flow was exceeded, and then graphically plotting the results. However, because the fecal coliform standard is seasonal and is applicable only between the months of May and October, flows not recorded during this time period were omitted from the analyses. The estimated daily stream flows were then multiplied by the more conservative water quality standard of 200 colony forming units (cfu)/100mL (as a daily maximum) to generate load duration curves for each segment. The load duration curves are graphical displays of the maximum allowable load of fecal coliform across all reported flow values for a given stream segment.

To assess primary contact use, Illinois EPA used all fecal coliform bacteria from water samples collected in May through October, for data from 2000 and beyond. Therefore, fecal coliform data collected from each impaired segment between May and October for the most recent years of available data (typically 2000-2014) were compiled from data amassed during Stage 1 of TMDL development. The existing Stage 1 dataset was then supplemented with available additional data collected since the completion of the Stage 1 report. These data were then paired with the corresponding daily average flow for each sampling date and plotted against the load duration curve. The resulting load duration curve figures for each impaired segment depict the maximum allowable load at each flow level along with the observed fecal coliform loads based on sample data (**Figures 1-6 through 1-13**).

Figure 1-6: Thorn Creek (HBD-02) Fecal coliform Load Duration Curve (May through October)

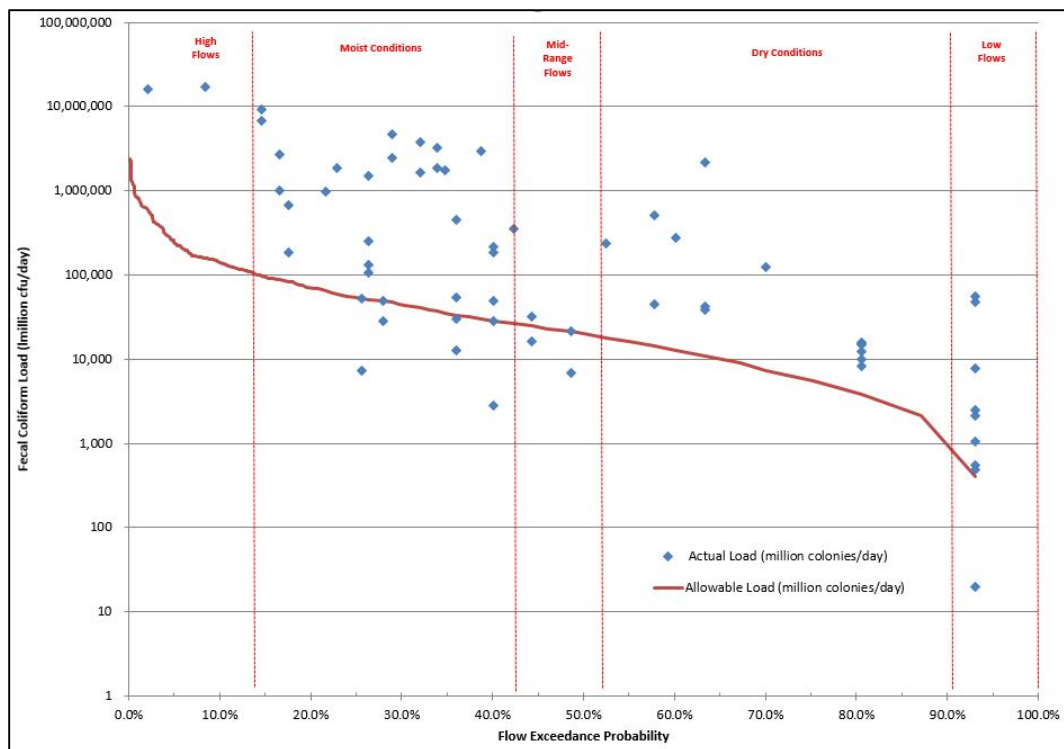

Figure 1-7: Thorn Creek (HBD-03) Fecal coliform Load Duration Curve (May through October)

Figure 1-8: Thorn Creek (HBD-04) Fecal coliform Load Duration Curve (May through October)

Figure 1-9: Thorn Creek (HBD-05) Fecal coliform Load Duration Curve (May through October)

Figure 1-10: Thorn Creek (HBD-06) Fecal coliform Load Duration Curve (May through October)

Figure 1-11: Butterfield Creek (HBDB-03) Fecal coliform Load Duration Curve (May through October)

Figure 1-12: Deer Creek (HBDC) Fecal coliform Load Duration Curve (May through October)

Figure 1-13: Deer Creek (HBDC-02) Fecal coliform Load Duration Curve (May through October)

The plots of available sample data against the load duration curves show that exceedances of the allowable fecal coliform load consistently occur under all flow conditions in each of the impaired segments. This suggests that the sources of fecal coliform loads into impaired segments in the Thorn Creek watershed occur during both higher flow conditions, likely in response to overland runoff and urban stormwater resulting from precipitation events, as well as under lower flow conditions, likely in response to point source discharges. **Appendix D** contains the spreadsheets used for the calculations of the load duration curves for fecal coliform in the impaired segments.

1.5.2.3 Chloride TMDLs for Streams

Load duration curves for chloride were also developed to assess TMDLs for the impaired segments (Thorn Creek HBD-04 and HBD-06) using the flow duration curves generated as described above. The flows used in development of the flow duration curve were then multiplied by the applicable water quality standard for chloride (500 mg/L) to generate a load duration curve for chloride for each segment.

Chloride data from 2000 and beyond queried from USEPA STORET, Illinois EPA, MWRD, TCSD and other sources were paired with the corresponding flows for the sampling dates and plotted against the load duration curves. The resulting load duration curve figures developed for each impaired segment depict the maximum allowable chloride load at each flow level along with the actual chloride loads based on observed sample data (**Figures 1-14** and **1-15**).

Figure 1-14: Thorn Creek (HBD-04) Chloride Load Duration Curve

Figure 1-15: Thorn Creek (HBD-06) Chloride Load Duration Curve

Actual loads in excess of the TMDL endpoints occur for only seven of the 274 samples for HBD-04, and for only one of the 113 samples for HBD-06. For HBD-04, excess loads occur under moist, mid-range, and dry flow conditions (but not high or low flow conditions). For HBD-06, the one exceedance occurred under moist conditions. In general, exceedances of the allowable load for chloride did not occur under extremely high or extremely low flows. This trend is consistent with the typical source of chloride loads which is runoff containing road and sidewalk de-icing compounds during winter months. Climate data shows that winter months generally have less extreme high flow runoff events. Further discussion of the likely sources of chloride loads in the Thorn Creek watershed is provided in **Sections 2** and **3** of this report. Spreadsheets used for the calculation of chloride load duration curves are provided in **Appendix D**.

1.5.2.4 Zinc TMDLs for Streams

A load duration curve for zinc (dissolved) was developed to assess TMDLs for the impaired segment (Thorn Creek HBD-02) using the flow duration curves generated as described above. The flows used in development of the flow duration curve were then multiplied by the applicable water quality standard for dissolved zinc (93 µg/L) to generate a load duration curve for zinc for the impaired segment.

Dissolved zinc data queried from USEPA STORET, Illinois EPA, MWRD, TCSD and other sources were paired with the corresponding flows for the sampling dates and plotted against the load duration curve. The resulting load duration curve figure developed for the impaired segment depicts the maximum allowable zinc load at each flow level along with the actual zinc loads based on observed sample data (**Figure 1-16**).

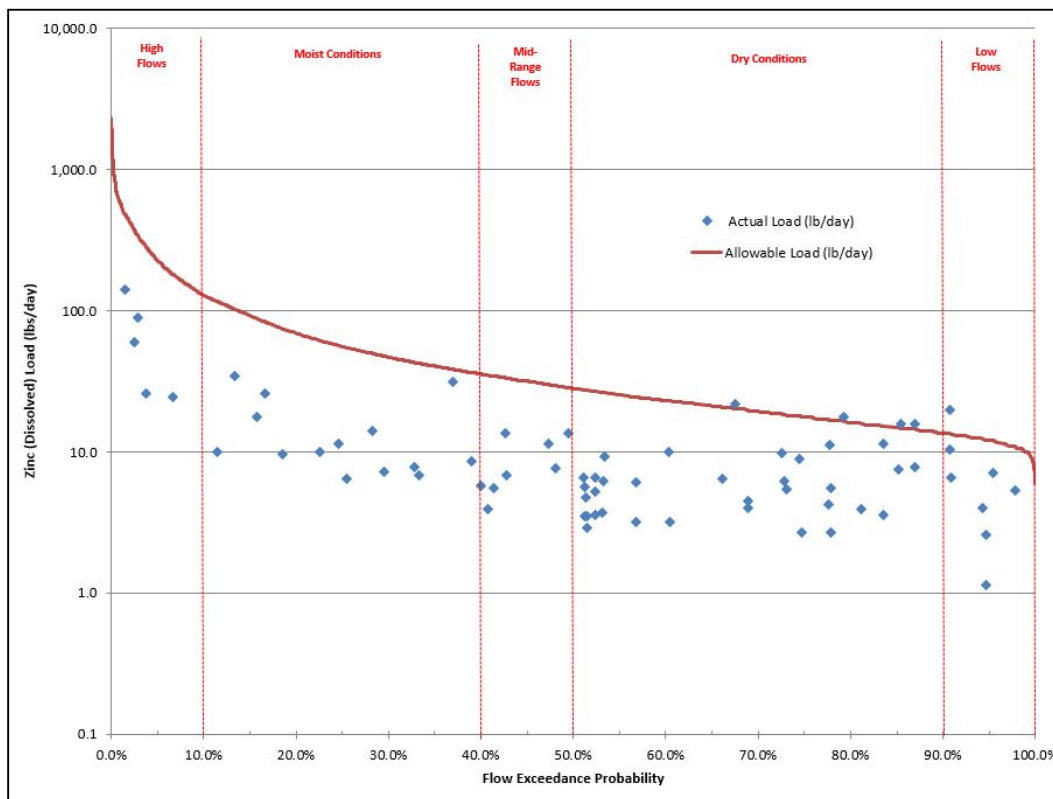

Figure 1-16: Thorn Creek (HBD-02) Zinc Load Duration Curve

The plots of available sample data against the load duration curve show that exceedances of the allowable zinc load occur only under dry and low flow conditions. This suggests that the primary sources of zinc loads into the impaired segment in the Thorn Creek watershed are not runoff related. Further discussion of the likely sources of zinc load in the Thorn Creek watershed is provided in **Sections 2** and **3** of this report. Spreadsheets used for the calculation of zinc load duration curves are provided in **Appendix D**.

1.5.2.5 Silver TMDLs for Streams

A load duration curve for silver (total) was developed to assess TMDLs for the impaired segment (Thorn Creek HBD-02) using the flow duration curve generated as described above. The flows used in development of the flow duration curve were then multiplied by the applicable water quality standard for silver (5.0 µg/L) to generate a load duration curve for silver for the impaired segment.

Silver data queried from USEPA STORET, Illinois EPA, MWRD, TCSD and other sources were paired with the corresponding flows for the sampling dates and plotted against the load duration curve. The resulting load duration curve figure developed for the impaired segment depicts the maximum allowable silver load at each flow level along with the actual silver loads based on observed sample data (**Figures 1-17**). Note that all non-detect results are assigned a zero lbs/day load in this calculation and are not shown on the plot.

Figure 1-17: Thorn Creek (HBD-02) Silver Load Duration Curve

Actual loads in excess of the TMDL endpoints occur for only four of 272 samples for HBD-02. One exceedance occurred under high flow conditions and three exceedances occur under dry or low flow conditions suggesting that the primary source of silver loads into the impaired segment in the Thorn Creek watershed may be associated with point sources or in response to overland runoff and urban stormwater resulting from precipitation events. However, since only one exceedance was documented at higher flows, it is difficult to attribute the loading definitively to higher flow conditions.

Further discussion of the likely sources of silver load in the Thorn Creek watershed is provided in **Sections 2** and **3** of this report. Spreadsheets used for the calculation of silver load duration curves are provided in **Appendix D**.

1.5.2.6 TSS and Sedimentation/Siltation LRSs for Streams

A load duration curve was developed for TSS for Thorn Creek segment HBD-02 and for sedimentation/siltation impairments to North Creek segment HBDA-01 and Deer Creek segment HBDC-02. Numeric standards do not exist for TSS or sedimentation and siltation impairments in streams, so the watershed-specific LRS target values provided by Illinois EPA of 72.7 mg/L for TSS and 61.6 mg/L of NVSS were used to develop the load duration curves for these impairments. NVSS is a surrogate analyte related to TSS (calculated as the difference of TSS minus volatile suspended solids in paired samples) that is currently used by Illinois EPA to develop LRSs for impairments associated with high sedimentation and siltation.

TSS and NVSS data queried from USEPA STORET, Illinois EPA, MWRD, TCSD and other sources were paired with the corresponding flow for the sampling dates and plotted against the load duration curves. The resulting load duration curve figures developed for each impaired segment depict the TSS or NVSS load that each stream segment can receive at each flow level while remaining below the respective LRS targets. The figures also include the actual TSS or NVSS loads under various flow regimes based the available sample data (**Figures 1-18** through **1-20**).

Only eight samples of NVSS exist for segment HBDA-01, with only one exceeding the allowable load, under moist conditions. Only two samples of NVSS exist for segment HBDC-02, with only one exceeding the allowable load, under dry conditions. It is therefore not possible to identify the major driver of sedimentation/siltation impairments in each of these segments. **Appendix D** contains spreadsheets used for the calculation of each of these load duration curves.

Figure 1-18: Thorn Creek (HBD-02) TSS Load Duration Curve

Figure 1-19: North Creek (HBDA-01) NVSS Load Duration Curve

Figure 1-20: Deer Creek (HBDC-02) NVSS Load Duration Curve

1.5.3 BATHTUB Development for Sauk Trail Lake Impairments Caused by Total Phosphorus

Sauk Trail Lake (RHI) is a small, man-made lake along the mainstem of Thorn Creek. It was created in 1923 by damming Thorn Creek, and has a current surface area of 28.8 acres. The lake is primarily used for recreational purposes, and is listed as impaired by total phosphorus. No point sources discharge to this waterbody. The TMDL target for total phosphorus is 0.05 mg/L.

The BATHTUB model was used to develop the total phosphorus TMDL for Sauk Trail Lake. BATHTUB has three primary input interfaces: global, reservoir segment(s), and watershed inputs. The individual inputs for each of these interfaces are described in the following sections along with watershed and operational information for the lake.

TMDL analysis for total phosphorus in Sauk Trail Lake involved the use of observed data coupled with the Rational Method as inputs to the BATHTUB models. This method required inputs from several sources including online databases and GIS-compatible data.

1.5.3.1 Global Inputs

Global inputs represent atmospheric contributions of precipitation, evaporation, and atmospheric phosphorus. The long-term average annual precipitation in the watershed near the Sauk Trail Lake dam is estimated at 38.11 inches based on data from the Park Forest Illinois State Water Survey (ISWS) Weather Station (site 116616) from 1953-2016. The average annual evaporation

in the watershed is estimated to be 20.76 inches, based on data from the nearest ISWS pan evaporation station, at the Chicago Botanical Gardens in Glencoe (site 11-1497).

The default atmospheric phosphorus deposition rate suggested in the BATHTUB model was used in absence of site-specific data, which is a value of 30 kilograms per square kilometer (kg/km^2)-year (U.S. Army Corps of Engineers 1999). This value is based on a compilation of available historical data and Illinois EPA believes that it is appropriate for use in this watershed where site-specific rates of deposition are not available.

1.5.3.2 Reservoir Segment Inputs

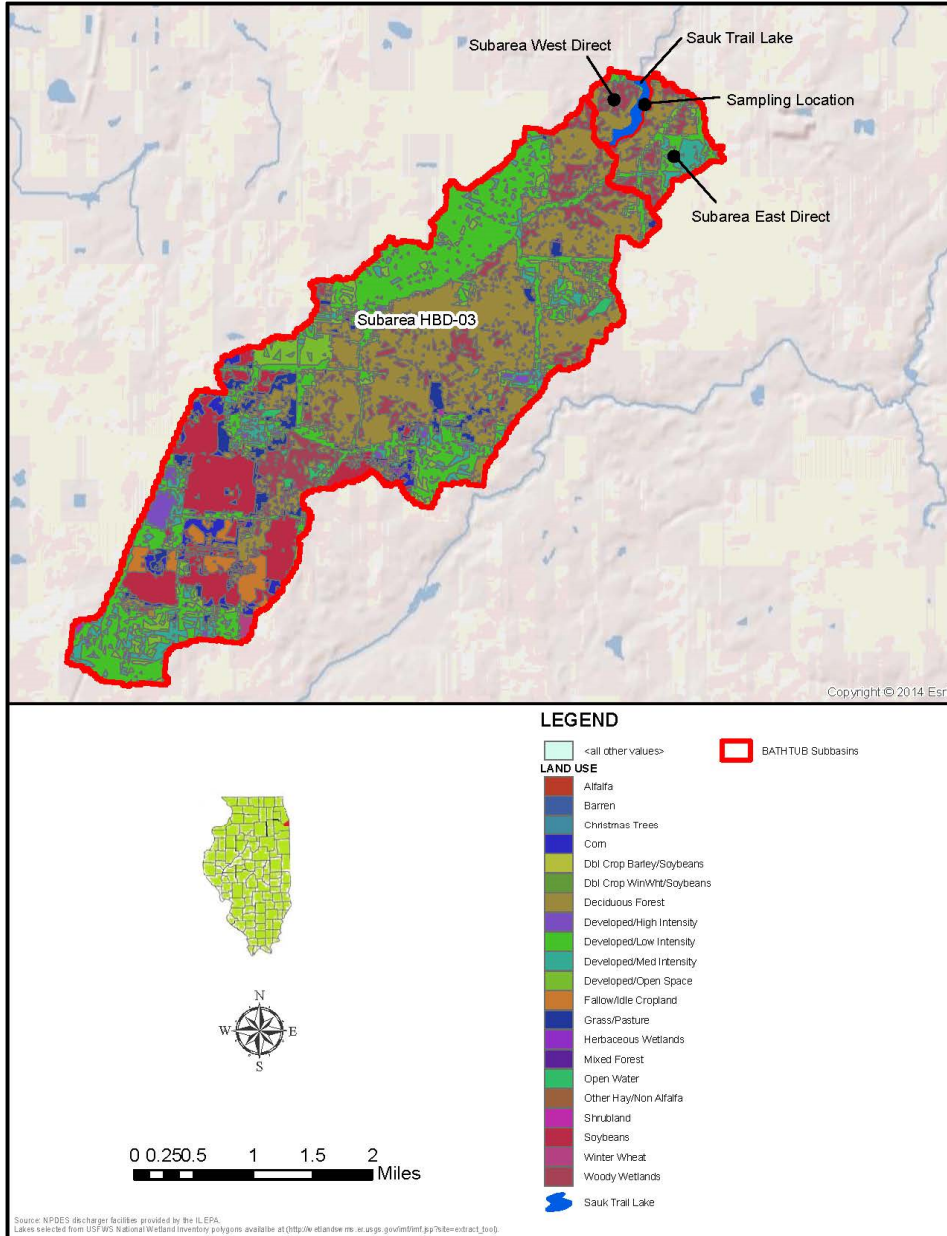

Reservoir segment inputs in BATHTUB are used for physical characterization of the reservoir. Sauk Trail Lake is modeled using one segment in BATHTUB. Segment inputs to the model include average depth, surface area, overall length, and average total phosphorus concentration near the surface of the lake. The lake depth was represented by the average of all depth measurements taken at the one water quality sampling station in the lake. Surface area was determined in GIS. These data are shown below (**Table 1-8**) for reference.

Table 1-8: Sauk Trail Lake Input Data

Segment	Surface Area (km^2)	Segment Length (km)	Average Depth (m)	Average Total Phosphorus at Surface (mg/L)
RHI	0.12	0.8	0.8	0.123

1.5.3.3 Tributary Inputs

Tributary inputs to BATHTUB include drainage area, flow, and total phosphorus loading. The drainage area of each tributary is equivalent to the basin or subbasin it represents, which was determined using GIS analyses. **Figure 1-21** shows the subbasin boundaries. The watershed was broken up into three subbasins for purposes of the model – the upper Thorn Creek tributary to Sauk Trail Lake (HBD-03), one small basin that discharges mainly sheet flow directly to the lake from the west (West Direct), and a small basin that directly discharges to the lake from the east (East Direct).

Note: Land Use data is from the 2015 Cropland Data Layer. Source: USDA.

Figure 1-21: Sauk Trail Lake (RHI) BATHTUB Sub-Basins

The Rational Method was used to estimate the runoff from each subbasin. The runoff coefficient and rainfall intensity used for the calculations were based on land use and the average monthly precipitation for the corresponding months for each season. The average wet and dry season flows for Thorn Creek were estimated using data from the downstream Thorn Creek gauge (USGS 05536215) by removing the TCSD’s discharge flow and then scaling by watershed area. The estimated flow from each subbasin is shown in **Table 1-9**.

Table 1-9: Sauk Trail Lake Tributary Inputs and Estimated Flows

Subbasin ID	Tributary Description	Subbasin Area (acres)	Estimated Average Flow Rate (cfs)	Estimated Average Total Phosphorus Concentration (mg/L)
Trib1: IL_RHI	West Direct	144	0.30	0.049
Trib2: IL_RHI – East	East Direct	364	0.76	0.156
Trib3: IL_HBD-03	Flow from Thorn Creek	5,603	11.7	0.142

Because there are limited available historical tributary concentration data, phosphorus loads from the contributing watershed were estimated based on land use data and the median annual export coefficients for each land use. Export coefficients for each land use category found in the Thorn Creek watershed are average values used for TMDLs in Illinois. The export coefficients for each land use are reported in lbs/acre/year, which can then be multiplied by the number of acres of each land use in each of the lake segment's subbasins to provide a total median phosphorus load into the reservoir.

1.5.3.4 BATHTUB Confirmatory Analysis

Historical water quality data for Thorn Creek are summarized in **Section 1.3.1** of this report and were used to help confirm model calculations. Although the analyses presented below do lend confidence to the modeling, they should not be considered a true model "calibration." Additional lake and tributary water quality and flow data are required to fully calibrate the model.

The Sauk Trail Lake BATHTUB model was initially simulated assuming default phosphorus kinetic parameters (assimilation and decay) and a small (5 mg/m²/day) internal phosphorus loading. When using these parameter settings, the BATHTUB model over-predicted the concentrations when compared to actual water quality data. To achieve a better match with actual water quality data, the internal loading and sedimentation coefficients were iteratively adjusted within reasonable ranges established in the available literature. Internal loading rates reflect nutrient recycling from bottom sediments while sedimentation coefficients reflect variations in sedimentation (settling) rates of individual reservoirs and portions of the reservoir as a function of flows, climate, morphology, and other factors.

As can be seen in **Table 1-10**, a strong match between predicted and observed concentration was achieved. A printout of the BATHTUB model files is provided in **Appendix E** of this report.

Table 1-10: Summary of Model Confirmatory Analysis – Sauk Trail Lake Total Phosphorus

Lake Site	Observed (mg/L)	Predicted (mg/L)	Internal Loading Rate (mg/m ² /day)
RHI1	0.123	0.123	0.5

Section 2

Total Maximum Daily Loads for the Thorn Creek Watershed

2.1 TMDL Endpoints for the Thorn Creek Watershed

The TMDL endpoints and LRS target values for impairments in the Thorn Creek watershed are summarized in **Table 2-1**. For all parameters except for DO, the concentrations must be less than the TMDL endpoint or LRS target value. The TMDL endpoints for fecal coliform and DO vary seasonally while all other endpoints are consistent throughout the year. All of these endpoints, except for the endpoint established for fecal coliform, are based on protection of aquatic life in the impaired segments in the Thorn Creek watershed. The TMDL endpoint for fecal coliform is based on protection of the primary body contact recreational use. The endpoints for total phosphorus and TSS in lakes are based on protection of the aesthetic quality designated use as well as the protection of aquatic life.

Parameters with numeric water quality standards are assessed via the TMDL process and the TMDL endpoints directly correlate to the lowest applicable water quality standard established for a given parameter. Select parameters without numeric water quality standards were assigned a watershed-specific LRS target value by Illinois EPA. The LRS targets are based on data from all stream segments within the HUC-10 basins of the watershed, as well as stream segments or lakes that closely border the watershed in neighboring HUC-10 basins, in order to best represent the land use, hydrologic, and geologic conditions unique to the watershed. Load reduction targets were calculated by Illinois EPA using data from stream segments for which the most current assessment shows full support for aquatic life and data that has passed quality assurance and quality checks within Illinois EPA and are in accordance with state and federal laws. These target values are not legally binding but are intended to serve as planning tools for overall water quality improvement strategies in the watershed.

Table 2-1: TMDL and LRS Endpoints for Impaired Constituents in the Thorn Creek Watershed

Segment Name/ID	Potential Cause of Impairment	Assessment Type	TMDL Endpoint or Target Value
Thorn Creek (HBD-02)	Dissolved Oxygen ¹	TMDL ²	6.0 mg/L weekly avg. (March -July) 5.0 mg/L daily minimum (March – July) 4.0 mg/L weekly avg. (August – February) 3.5 mg/L minimum (August-February)
	Silver	TMDL	5.0 µg/L
	Zinc	TMDL	355 µg/L (acute) ³ 93 µg/L (chronic) ³
	Fecal Coliform	TMDL	200 ⁽¹⁾ cfu/100ml (May – October)
	TSS	LRS	72.7 mg/L

Section 2 • Total Maximum Daily Loads for the Thorn Creek Watershed

Segment Name/ID	Potential Cause of Impairment	Assessment Type	TMDL Endpoint or Target Value
Thorn Creek (HBD-03)	Dissolved Oxygen	TMDL ²	6.0 mg/L weekly avg. minimum (March -July) 5.0 mg/L daily minimum (March – July) 4.0 mg/L weekly avg. (August – February) 3.5 mg/L minimum (August-February)
	Fecal Coliform	TMDL	200 ⁽¹⁾ cfu/100ml (May – October)
Thorn Creek (HBD-04)	Dissolved Oxygen	TMDL ²	6.0 mg/L weekly avg. minimum (March -July) 5.0 mg/L daily minimum (March – July) 4.0 mg/L weekly avg. (August – February) 3.5 mg/L minimum (August-February)
	Fecal Coliform	TMDL	200 ⁽¹⁾ cfu/100ml (May – October)
	Chloride	TMDL	500 mg/L
Thorn Creek (HBD-05)	Fecal Coliform	TMDL	200 ⁽¹⁾ cfu/100ml (May – October)
Thorn Creek (HBD-06)	Dissolved Oxygen	TMDL ²	6.0 mg/L weekly avg. minimum (March -July) 5.0 mg/L daily minimum (March – July) 4.0 mg/L weekly avg. (August – February) 3.5 mg/L minimum (August-February)
	Fecal Coliform	TMDL	200 ⁽¹⁾ cfu/100ml (May – October)
	Chloride	No TMDL Developed	No longer impaired – recommended for delisting
North Creek (HBDA-01)	Dissolved Oxygen	TMDL ²	6.0 mg/L weekly avg. minimum (March -July) 5.0 mg/L daily minimum (March – July) 4.0 mg/L weekly avg. (August – February) 3.5 mg/L minimum (August-February)
	Sedimentation/Siltation	LRS	61.6 mg/L of NVSS
Butterfield Creek (HBDB-03)	Fecal Coliform	TMDL	200 ⁽¹⁾ cfu/100ml (May – October)
Deer Creek (HBDC)	Fecal Coliform	TMDL	200 ⁽¹⁾ cfu/100ml (May – October)
Deer Creek (HBDC-02)	Dissolved Oxygen	TMDL ²	6.0 mg/L weekly avg. minimum (March -July) 5.0 mg/L daily minimum (March – July) 4.0 mg/L weekly avg. (August – February) 3.5 mg/L minimum (August-February)
	Fecal Coliform	TMDL	200 ⁽¹⁾ cfu/100ml (May – October)
	Sedimentation/Siltation	LRS	61.6 mg/L of NVSS
Sauk Trail Lake (RHI)	Dissolved Oxygen	TMDL for Total Phosphorus	0.05 mg/L TP
	Total Phosphorus	TMDL	
	Sedimentation/Siltation	LRS	61.6 mg/L of NVSS
	TSS	LRS	72.7 mg/L

⁽¹⁾ Geometric mean based on a minimum of five samples taken over not more than a 30-day period.

⁽²⁾ TMDL developed for primary contributing factors to low DO impairment as identified by QUAL2K modeling.

⁽³⁾ Zinc acute and chronic standards were calculated based on water hardness, per the formulas codified in the Illinois Water Quality Standards, Section 302.208(e). An average water hardness was determined based on all hardness water quality samples available. Average hardness was 362 mg/L. Calculations for average hardness and acute and chronic zinc standards are included in **Appendix F**.

2.2 Pollutant Sources and Linkages

Potential pollutant sources for impaired lakes and streams in the Thorn Creek watershed include both point and nonpoint sources. Pollutants impairing the Thorn Creek watershed include fecal coliform, chloride, zinc, silver, dissolved oxygen, and total phosphorus.

Sources of Fecal Coliform

Point sources of fecal coliform consist of two large POTWs (Thorn Creek Sanitary District STP and Aqua Illinois – University Park WWTF), two excess-flow POTWs (Homewood Excess Flow Treatment Plant and Park Forest Excess Flow Facility), two small mobile home park treatment plants (Ely’s Mobile Home Park STP and Paradise Park MHP STP), and permitted MS4 outfalls throughout the watershed. The facilities and outfalls are located both on tributaries of the impaired segments and, in some cases, directly discharge effluent to the impaired stream segments.

Likely nonpoint sources of fecal coliform in the watershed include wildlife waste, domestic pet waste, and overland stormwater runoff. Other nonpoint sources for fecal coliform can include septic systems. While the entirety of the watershed is currently within the service area of a municipal sewer system, functional or abandoned septic systems potentially still exist within the watershed, the existence and prevalence of which is not known.

Sources of Chloride

There are twelve NPDES permitted point sources present within the Thorn Creek watershed, and these facilities are located both on tributaries of the impaired segments and, in some cases, they directly discharge effluent to the impaired stream segments. Only two of the listed facilities, Aqua Illinois – University Park WWTF and Park Forest WTP have discharge monitoring requirements for chloride.

Land use in the Thorn Creek watershed is approximately 58% urban overall, with denser urban areas towards the downstream end of the watershed. Nonpoint chloride sources may therefore originate from road de-icing activities using chloride salts. These salts can accumulate in soils adjacent to roadways and then become a source of chloride in non-winter months.

Sources of Silver and Zinc

Point sources of zinc within the Thorn Creek watershed tributary to segment HDB-02 include Aqua Illinois – University Park WWTF. There are no identified point sources that have permit limits or monitoring requirements for silver.

Nonpoint sources of zinc include aging galvanized iron and steel, road salt, and tire wear (Schueler and Shepp 1993). Runoff from undeveloped, park, and agricultural lands are potential

nonpoint sources of zinc and silver pollution to the impacted stream segment, since both metals can be carried on sediments.

Sources of Phosphorus and Oxygen Demanding Materials

Point sources discharging to impaired streams within the Thorn Creek watershed include municipal sewage treatment facilities and industrial dischargers. **Table 1-6** contains permit information on the treatment facilities, as well as model input parameters used in the QUAL2K modeling discussed in **Section 2** of this report. As discussed in **Section 1.5.2.6**, two large municipal treatment facilities discharge to, or upstream of, segments HBD-02, HBD-04, HBD-06, HBCD, and/or HBDC-02. Only one facility is currently subject to effluent limits for total phosphorus, and the other is only required to monitor for this parameter. The two existing POTW facilities also discharge oxygen-demanding materials, as measured by BOD. There are also numerous smaller dischargers that discharge to the streams in the watershed. The facilities discharge to tributaries of the impaired segments, or in some cases, directly to the impaired stream segments.

Potential stormwater-related inputs of nutrients to the impacted streams in the watershed include MS4 and non-MS4 urban runoff, and runoff from agricultural, undeveloped, and park lands. In addition, inputs are often caused by nutrient applications in urban settings, such as fertilizer inputs on lawns, golf courses, and other intensively used and maintained landscapes. Nutrients dissolve in water, or adsorb to soils, and enter waterways with runoff and erosion, resulting in excessive growth of algae and other aquatic plants. This impairs aesthetics, water quality, and recreational potential.

Load duration curves were developed for fecal coliform, chloride, silver, and zinc TMDLs, as well as for TSS and sedimentation/siltation LRSs in stream segments. Load duration curves are useful in that they provide a link between historical sampling values and hydraulic condition. **Table 2-2** shows the example source area/hydrologic condition considerations developed by USEPA. Pollutant sources for TSS in lakes are likely similar to those identified for stream segments impaired by these parameters.

Table 2-2: Example Source Area/Hydrologic Condition Considerations (USEPA 2007)

Contributing Source Area	Duration Curve Zone				
	High Flow	Moist	Mid-Range	Dry	Low Flow
Point Source				M	H
Onsite Wastewater System			H	M	
Riparian Areas		H	H	H	
Stormwater: Impervious Areas		H	H	H	
Combined sewer overflows	H	H	H		
Stormwater: Upland	H	H	M		
Bank Erosion	H	M			

Note: potential relative importance of source area to contribute loads under given hydrologic conditions (H: High, M: Medium)

Other pollutant sources and their linkages to Sauk Trail Lake were established through the modeling (BATHTUB) as discussed in **Section 1**. Modeling indicated that loads of total phosphorus may originate from internal and external sources. Overall potential sources of

nutrients in the impaired lake watersheds include point and nonpoint sources such as runoff from surrounding developed areas, forest and parkland, waterfowl, and internal loading from lake sediments. Nutrients bound in eroded soils and plant materials, or in dissolved form, are introduced to the waterbodies through runoff from precipitation events. Once in the waterbodies, internal cycling of nutrients between the water column and underlying lake sediments can exacerbate the nutrient impairment problem. Pollutant sources and linkages for stream segments impaired by low DO (Thorn Creek HBD-02, Thorn Creek HBD-03, Thorn Creek HBD-04, Thorn Creek HBD-06, North Creek HBDA-01, and Deer Creek HBDC-02) were established through the QUAL2K modeling effort. Modeling indicated that low DO levels in this watershed are driven primarily by a combination of low reaeration and high SOD. The high SOD appears to be a result primarily of diffuse source CBOD and NBOD loading in the upper reaches of the watershed. Further pollutant source discussion is provided throughout this section and implementation activities to reduce loading from the potential sources are outlined in **Section 3**.

2.3 TMDL Allocation

The TMDLs for impaired segments in the Thorn Creek watershed address the following equation:

$$\text{TMDL} = \text{LC} = \Sigma \text{WLA} + \Sigma \text{LA} + \text{MOS} + \text{RC}$$

where:	LC	=	Loading capacity the maximum amount of pollutant loading a water body can receive without violating water quality standards
	WLA	=	Waste load allocation the portion of the TMDL allocated to existing or future point sources
	LA	=	Load allocation – the portion of the TMDL allocated to existing or future nonpoint sources and natural background
	MOS	=	Margin of safety an accounting of uncertainty about the relationship between pollutant loads and receiving water quality
	RC	=	Reserve capacity – the portion of the load explicitly set aside for future population growth and additional development in the watershed

Each of these elements are discussed in this section, as well as consideration of seasonal variation in the TMDL calculation.

2.3.1 Fecal Coliform TMDL

Thorn Creek segments HBD-02, HBD-03, HBD-04, HBD-05, and HBD-06; Butterfield Creek segment HBDB-03; and Deer Creek segments HBDC and HBDC-02 in the Thorn Creek watershed are listed for impairment of the general use standard caused by fecal coliform. Load duration curves were developed (see **Section 1**) to determine load reductions needed to meet the instream water quality standards under varying flow scenarios for each segment.

2.3.1.1 Loading Capacity

The LC is the maximum amount of fecal coliform that Thorn Creek segments HBD-02, HBD-03, HBD-04, HBD-05, and HBD-06; Butterfield Creek segment HBDB-03; and Deer Creek segments HBDC and HBDC-02 can receive and still maintain compliance with the water quality standards. The allowable fecal coliform loads that can be generated in the watershed and still maintain the

geometric mean standard of 200 cfu/100mL were determined with the methodology discussed in Section 1. The fecal coliform LC according to flow is presented in Table 2-3.

2.3.1.2 Seasonal Variation

Consideration of seasonality is inherent in the load duration analysis. Because the load duration analysis represents the range of expected stream flows, the TMDL has been calculated to meet the standard during all flow conditions. In addition, seasonality is addressed because the TMDL has

been calculated to address loading only when the seasonal standard is applicable (May through October). The fecal coliform standard must be met under all flow scenarios within the recreation season.

Table 2-3: Estimated Fecal Coliform Loading Capacities Under Various Flow Conditions for Streams in the Thorn Creek Watershed

Estimated Mean Daily Flow (cubic feet per second [cfs])	Load Capacity (mil col/day)
5	24,446
10	48,931
50	244,657
100	489,314
500	2,446,572
1,000	4,893,143
5,000	24,465,715
10,000	48,931,430
15,000	73,397,146

2.3.1.3 Margin of Safety

The MOS can be implicit (incorporated into the TMDL analysis through conservative assumptions) or explicit (expressed in the TMDL as a portion of the loadings) or a combination of both. The MOS incorporated into the fecal coliform TMDL analyses are implicit, as the analyses used the more conservative 200 cfu/100mL standard and did not consider die-off of bacteria, which is likely occurring in the system but unquantified.

2.3.1.4 Waste Load Allocation

WLAs for fecal coliform TMDLs are applied to individually permitted facilities and municipal separate storm sewer discharges (MS4s) that exist in the Thorn Creek watershed, as described below.

Individual NPDES permitted facilities

There are five major individual NPDES permitted dischargers within the Thorn Creek watershed. Four of the major dischargers are municipal publicly owned treatment works (POTWs) (Thorn Creek Basin Sanitary District STP, Aqua Illinois – University Park WWTF, Homewood Excess Flow Treatment Plant and Park Forest Excess Flow Facility) and one is an industrial discharger (Chicago Heights Steel). There are also a number of minor individual NPDES permitted dischargers, including two mobile home park (MHP) treatment plants (Ely’s Mobile Home Park STP and Paradise Park MHP) and several other dischargers (Hanson Material Service Yard 41, Mid-West Manufacturing LLC, Innophos Inc., Park Forest WTP and Village of Lynwood CCDD). Details on each NPDES permit and the directly impacted segments are provided in Table 2-4. The four POTWs and two MHPs currently have permit limits for fecal coliform bacteria of 400 cfu/100ml as a daily maximum value. However, Illinois EPA is using the instream water quality standard of 200 cfu/100ml as a geometric mean to develop fecal coliform WLAs for each of the permitted POTWs discharging to the impaired segment. The industrial facilities do not have permit limits for fecal coliform and due to the nature of the process water being discharged, are not considered to have reasonable potential to discharge elevated concentrations of fecal coliform and therefore were not assigned WLAs for this parameter.

Each POTW facility's design maximum flow (DMF) was used to calculate the WLA during the highest 40% of in-stream flow conditions while the facility's design average flow (DAF) was used to calculate the WLA at lower stream flow levels (see discussion in **Section 2.3.1.5**). The use of the DMF in place of the more common DAF at higher flow conditions for each point source facility in the WLA calculations serves as an additional conservative measure in the TMDL calculations. This methodology essentially allows for each facility to use the entire treatment and discharge capacity available while still remaining within the WLA.

The DAFs and DMFs were multiplied by the geometric mean water quality standard of 200 cfu/100 ml for fecal coliform to establish the WLA for that facility, shown in **Table 2-4**. WLAs from point source discharges are applied to each discharge point for the segment receiving the discharge or the nearest impaired segment downstream of the discharge. WLAs are not calculated for additional impaired segments downstream of the receiving segment, as the segment nearest the discharge will mathematically have the least assimilative capacity, and the calculation of WLAs for this segment will be protective of all downstream segments.

Table 2-4: Fecal Coliform WLAs for NPDES Permitted Point Sources in the Thorn Creek Watershed

Facility	NPDES Permit Number	Applicable Stream Segment	DAF (MGD)	WLA-DAF (mil. col/Day)	DMF (MGD)	WLA-DMF (mil. col/Day)

Park Forest WTP	ILG640194	HBD-05	--	n/a ³	--	n/a ³

¹ Maximum discharge rate when actively discharging within last five years, applied to high flow conditions only.

² Design flow of this facility.

³ No effluent limit for fecal coliform for this facility, no reasonable potential for elevated fecal coliform concentrations in discharge.

The permitted effluent limit for fecal coliform at all of the POTWs in this watershed is currently based on the 400 cfu/100ml daily maximum standard (not to be exceeded by more than 10% of samples collected in a 30-day period), which is not the most conservative water quality standard applicable to these stream segments. The most stringent applicable standard, and the one used as a TMDL endpoint for this watershed is the 200 cfu/100ml monthly geometric mean water quality standard for fecal coliform was used to establish the WLA for each facility. This limit will be included as a requirement in future NPDES permits issued for these facilities.

Furthermore, under certain low stream flow conditions, the effluent discharge from the treatment facilities may represent the only source of flow in the receiving stream. Under these low flow conditions, large proportions of the discharge will be lost to evaporation and infiltration into the stream bed, limiting the potential for conveyance of discharged materials into downstream reaches. Because WLA calculations are based on the permitted flow for each facility, under low to mid-level flow conditions the WLA can be overestimated and the resulting calculations will show WLA exceeding the LC for the receiving stream. In this case, at flow levels where the WLA exceeds the LC, the WLA was set equal to the LC at that flow level and the resulting nonpoint source (LA) allowable loads are zero.

MS4 Discharges

MS4s represent runoff from municipal areas with separate stormwater sewer systems. MS4s are regulated discharges and therefore, are allocated through WLAs, rather than LAs. WLAs for MS4s are calculated by first determining the total area within a municipality’s boundaries that lies within the target watershed using GIS analyses and geographic data for municipal boundaries from the U.S. Census Department (2000).

The proportion of total MS4 area to total watershed area was then calculated for each sub-watershed. This proportion was then used to migrate loads from previously calculated LAs for overland runoff to WLAs for MS4 areas in each flow category. This process effectively transfers MS4 load allocations for overland runoff from non-regulated sources described as LAs to the WLA for regulated sources of contaminants. As MS4 allocations are tied to overland runoff in urban areas, they are therefore related to higher flow conditions in the stream. As a result, the WLAs for MS4s are only applied to the upper 50% of flow categories (mid-range to high flows) for each segment. The total MS4 load allocations for fecal coliform that are applied based on the proportion of each municipality within each impaired reach’s subbasin are shown for each applicable flow **category in Tables 2-5 through 2-12**. It should be noted that allocations based on proportional area may not accurately reflect the distribution of various sources of pollutant loads (runoff, possible elicited discharges, etc.) and may need to be adjusted upon further investigation of loading from each MS4 discharge.

2.3.1.5 Reserve Capacity

A portion of the fecal coliform loading capacity may be set as a RC to allow for future population growth and development. In the case of Thorn Creek segments HBD-02, HBD-03, HBD-04, HBD-05, and HBD-06; Butterfield Creek segment HBDB-03; and Deer Creek segments HBDC and HBDC-02, an RC was included implicitly within the WLA. While the population within some portions of the Thorn Creek watershed is projected to increase between 2010 and 2040 (CMAP 2010), this

increase has largely been anticipated by the POTWs in the watershed and is reflected in the design capacities permitted for each facility. The use of DMF in place of the more common DAF at higher flow conditions for each point source facility in the WLA calculations serve as conservative measures in the TMDL calculations and accounts for the population growth in the watershed as anticipated by the POTWs' facility plans. This methodology provides implicit RC for each facility and allows for the use of the entire treatment and discharge capacity available while still remaining within the WLA. Future growth requiring expansion above and beyond the current capacity of the POTWs discharging to this watershed is not anticipated at this time. Population growth in the watershed is not expected to directly impact fecal coliform contributions from non-point sources.

2.3.1.6 Load Allocation and TMDL Summary

Table 2-13 shows a summary of the fecal coliform TMDL for Thorn Creek segment HBD-02. This segment has one point source discharge, Paradise Park MHP STP (IL0026794) that was assigned a WLA for fecal coliform. This discharge has a relatively small flow, and its permitted design average and DMFs were used along with the WQS of 200 cfu/100ml as a geometric mean to calculate the WLAs. The remainder of the WLA applied to this segment's TMDL are related to the MS4 areas as discussed in **Section 2.3.1.4**. Under low flow and dry conditions, the calculated WLA does not include MS4s as these sources are precipitation and flow dependent.

Table 2-13: Fecal Coliform TMDL for Thorn Creek Segment HBD-02

Zone	Flow Exceedance Range (%)	LC (mil col/day)	WLA (mil col/day)	LA (mil col/day)	MOS	Actual Load ¹ (mil col/day)	Percent Reduction Needed (%)

¹ Actual Load was calculated using the 90th percentile of observed fecal coliform concentrations in a given flow range (USEPA 2007)

Table 2-14 shows a summary of the fecal coliform TMDL for Thorn Creek segment HBD-03. All of the WLA applied to this segment's TMDL are related to the MS4 areas discussed in **Section 2.3.1.4**. There are no permitted point sources in or upstream of segment HBD-03. Under low flow and dry conditions, the calculated WLA does not include MS4s as this source is precipitation and flow dependent.

Table 2-14: Fecal Coliform TMDL for Thorn Creek Segment HBD-03

Zone	Flow Exceedance Range (%)	LC (mil col/day)	WLA (mil col/day) ²	LA (mil col/day)	MOS	Actual Load ¹ (mil col/day)	Percent Reduction Needed (%)

² WLA for MS4s only applied in the mid to high flow categories, no other WLA required.

Table 2-16 shows a summary of the fecal coliform TMDL for Thorn Creek segment HBD-05. This segment has one point source discharge that contributes fecal coliform, Park Forest Excess Flow Facility (IL0047562). According to facility operators, the facility operates when the TCSD interceptor sewer flow is greater than 2.9 MGD and the DAF of the facility is 2.8 MGD. The permitted DMF was listed as “no limit” for the Park Forest Excess Flow Facility. In order to calculate the high flow WLA, the DAF of the facility was used (2.8 MGD), along with the 200cfu/100ml geometric mean water quality standard. The remainder of the permitted point sources in the watershed discharge to segments upstream of HBD-05 and are accounted for in TMDLs developed for the segment initially receiving the discharge. The remainder of the WLA applied to this segment’s TMDL are related to the MS4 areas as discussed in **Section 2.3.1.4**. Under low flow and dry conditions, the calculated WLA does not include MS4s as these sources are precipitation and flow dependent.

Table 2-16: Fecal Coliform TMDL for Thorn Creek Segment HBD-05

Zone	Flow Exceedance Range (%)	LC (mil col/day)	WLA (mil col/day) ²	LA (mil col/day)	MOS	Actual Load ¹ (mil col/day)	Percent Reduction Needed (%)

	80 - 90	5,374	0	5,374	implicit	204,433	97%
Low Flow	90 - 100	1,857	0	1,857	implicit	328,531	99%

¹ Actual Load was calculated using the 90th percentile of observed Fecal coliform concentrations in a given flow range (USEPA 2007)

² WLA for MS4s only applied in the mid to high flow categories, no other WLA required.

A summary of the fecal coliform TMDL for Thorn Creek segment HBD-06 is provided in **Table 2-17**. This segment is an effluent dominated stream receiving much of its flow from the Thorn Creek Basin Sanitary District STP (IL0027723), particularly at lower flow levels. The WLA was calculated using the appropriate design flows for the facility and the 200cfu/100ml geometric mean water quality standard. Under some flow conditions, the calculated WLA from this point source alone is greater than the calculated LC, resulting in insufficient available WLA for the MS4 and zero available LA. In some lower flow categories that do not include MS4 loads, there is also insufficient LC to absorb the entire WLA from the Thorn Creek Basin Sanitary District STP and WLAs were set to the LC. These anomalies are a product of the disproportionately high discharge flows associated with using design flows under all stream flow conditions. In order to reconcile this and provide more accurate load allocation numbers, the WLA was set equal to the LC for these lower flow categories.

Table 2-17: Fecal Coliform TMDL for Thorn Creek Segment HBD-06

Zone	Flow Exceedance Range (%)	LC (mil col/day)	WLA (mil col/day)	LA (mil col/day)	MOS	Actual Load ¹ (mil col/day)	Percent Reduction Needed (%)
High	0 - 10	611,316	541,324	69,992	Implicit	103,443,719	99%

* All available loading capacity assigned to WLA based on calculations using permitted flows and effluent limits.

¹ Actual Load was calculated using the 90th percentile of observed Fecal coliform concentrations in a given flow range (USEPA 2007)

Table 2-18 shows a summary of the fecal coliform TMDL for Butterfield Creek segment HBDB-03. This segment has two point source discharges, Homewood Excess Flow Treatment Plant (IL0029211) and Ely’s Mobile Home Park STP (IL56065) that were assigned a WLA for fecal coliform discharges to this segment. The Homewood facility operates at high flows, when Thorn Creek Basin Sanitary District STP is receiving its maximum practical flow. The permitted DMF was listed as “no limit” for the Homewood Excess Flow Treatment Plant. In order to calculate the high flow WLA, the highest recorded facility flow of the past five years was used (18.5 MGD), along with the 200 cfu/100ml geometric mean water quality standard. Ely’s Mobile Home Park STP has a relatively small flow, and its permitted design average and design maximum flows were used along with the 200 cfu/100ml geometric mean water quality standard to calculate the WLAs. The remainder of the WLA applied to this segment’s TMDL are related to the MS4 areas as discussed in **Section 2.3.1.4**. Under low flow and dry conditions, the calculated WLA does not include MS4s as these sources are precipitation and flow dependent.

Dry	50 - 60	33,122	0	33,122	implicit	213,293	84%
	60 - 70	27,509	0	27,509	implicit	141,627	81%
	70 - 80	21,895	0	21,895	implicit	7,565	N/A
	80 - 90	17,403	0	17,403	implicit	146,991	88%
Low Flow	90 - 100	11,789	0	11,789	implicit	51,358	77%

¹ Actual Load was calculated using the 90th percentile of observed Fecal coliform concentrations in a given flow range (USEPA 2007)

² WLA allocations for MS4s only applied in the mid to high flow categories, no other WLA required.

2.3.2 Chloride TMDL

Thorn Creek Segments HBD-04 and HBD-06 are each listed for impairment caused by elevated chloride concentrations.

Only one exceedance (sample collected February 22, 2010) to the water quality standard has been reported at Segment HBD-06 out of 113 samples collected since 2000 (see Figure 1-15). In fact, Segment HBD-06 has only one impairment out of 325 samples since 1982. Prior data from 1970 – 1982 shows that there were 6 impairments from the mid-1970's to the early 1980's, so an impairment may have existed at this time. A grab sample has been collected most months on this segment from the early 1970's to 2012, for a total of 463 samples, so ample data exists. It seems that therefore that there is insufficient indication that this segment is currently impaired by chloride anymore, and therefore this segment is recommended for delisting for impairment caused by chloride.

A load duration curve was developed for the impaired segment HBD-04 (see **Section 1**) to determine load reductions needed to meet the instream water quality standard of 500 mg/L chloride across the full range of recorded flow levels.

2.3.2.1 Loading Capacity

The LC is the maximum quantity of chloride that the impaired segment can receive and still maintain compliance with the water quality standard. In order to determine the LC at various flow conditions, a range of flows were multiplied by the water quality standard (500 mg/L).

Table 2-21 contains the LCs for chloride under a range of flow conditions.

2.3.2.2 Seasonal Variation

Consideration to seasonality is inherent to load duration analysis. The total chloride water quality standard is not seasonal and the full range of expected flows is represented in the loading capacity table (**Table 2-21**). Therefore, the LC represents conditions throughout the year.

2.3.2.3 Margin of Safety

The MOS can be implicit (incorporated into the TMDL analysis through conservative assumptions), or explicit (expressed in the TMDL as a portion of the loadings), or a combination of both. An explicit MOS for the total chloride TMDL of 10% was included to account for some of the limited site-specific data available within the watershed. Ten percent is generally considered adequate to compensate for any uncertainty in the TMDLs developed using this methodology because the use of the load duration curve approach minimizes a great deal of uncertainty as the calculation of the loading capacity is simply a function of flow multiplied by the target value. Most of the uncertainty in the calculations is therefore associated with the estimated flows in the assessed segments which were based on extrapolating flows from a surrogate USGS gauge. The methodology employed in estimating watershed flows is discussed in **Section 1.5.2** of this document.

Table 2-21: Estimated Chloride Loading Capacities Under Various Flow Conditions for Streams in the Thorn Creek Watershed

Estimated Mean Daily Flow (cfs)	Load Capacity (lbs/day)
5	13,484
10	26,969
50	134,844
100	269,689
500	1,348,443
1,000	2,696,886
5,000	13,484,428
10,000	26,968,857
15,000	40,453,285

2.3.2.4 Waste Load Allocation

As with the fecal coliform TMDLs, the WLAs for chloride TMDLs apply to individually permitted facilities and MS4s that exist in the Thorn Creek watershed, as described below.

Individual NPDES permitted facilities

Only one permittee is close enough to segment HBD-04 to impact its chloride concentration (Thorn Creek Basin Sanitary District STP). This facility currently has no permit limits for chloride. The chloride instream water quality standard of 500 mg/L was combined with the facility's DAF and DMF to assign WLAs for this discharge. Details for chloride for this NPDES permit and the direct receiving segment is provided in **Table 2-22**.

Table 2-22: Chloride WLAs for NPDES Permitted Point Sources in the Thorn Creek Watershed

Facility	NPDES Permit Number	Applicable Stream Segment	DAF (MGD)	WLA-DAF (lbs/Day)	DMF (MGD)	WLA-DMF (lbs/Day)
Thorn Creek Basin Sanitary District STP	IL0027723	HBD-04	15.94	66,512	40.25	167,949

MS4 Discharges

MS4 discharges represent runoff from municipal areas with separate stormwater sewer systems. MS4 discharges are regulated discharges and therefore, are allocated through WLAs, rather than LAs. Chloride WLAs for MS4s were calculated in a manner consistent with the calculations performed for fecal coliform TMDLs (see **section 2.3.1.4**). The total MS4 load allocations for

chloride that are applied to each municipality within each impaired reach’s subbasin are shown for each applicable flow category in **Table 2-23**. It should be noted that allocations based on proportional area may not accurately reflect the distribution of various sources of pollutant loads and may need to be adjusted upon further investigation of loading from each MS4 discharge.

Table 2-23: WLA (lbs/Day) for MS4 Areas in Thorn Creek Segment HBD-04

Municipality	NPDES ID	MS4 Area in Watershed (acres)	High	Moist				Mid-Range	Dry				Low Flow
			0 - 10%	10 - 20%	20 - 30%	30 - 40%	40 - 50%	50 - 60%	60 - 70%	70 - 80%	80 - 90%	90 - 100%

2.3.2.5 Reserve Capacity

In the case of the chloride TMDL, an explicit RC was not included in the TMDL calculations due to the lack of point source loading of chloride from facilities directly impacted by population change believed to be occurring in the watershed. Non-point loads of chloride are not expected to increase as a result of typical levels of population growth anticipated within this watershed.

2.3.2.6 Load Allocation and TMDL Summary

Table 2-24 shows the summary of the chloride TMDL for segment HBD-04. This segment has one tributary point source discharge, Thorn Creek Basin Sanitary District STP (IL0027723) that was

assigned a WLA for chloride discharges to this segment. This discharger's permitted design average and design maximum flows were used along with the 500 mg/L limit to calculate the WLAs. The remainder of the WLA applied to this segment's TMDL is related to the MS4 areas as discussed in **Section 2.3.2.4**. Under low flow and dry conditions, the calculated WLA does not include MS4s as these sources are precipitation and flow dependent. Although individual samples collected in this segment have exceeded the instream water quality standard on several occasions, exceedences are relatively infrequent (approximately 2.6% of all samples) and do not result in a calculated percent reduction (based on the 90th percentile of recorded concentrations in each flow category) needed from any of the flow categories.

Table 2-24: Chloride TMDL for Thorn Creek (HBD-04)

Zone	Flow Exceedance Range (%)	LC (lbs/day)	WLA (lbs/day)	LA (lbs/day)	MOS - 10% of LC (lbs/day)	Actual Load ¹ (lbs/day)	Percent Reduction Needed (%)
High	0 - 10	1,248,747	773,045	350,827	124,875	816,132	None
Moist	10 - 20	493,949	343,039	101,515	49,395	256,731	None
	20 - 30	296,924	230,795	36,437	29,692	209,183	None
	30 - 40	213,675	183,368	8,940	21,367	161,817	None
Mid-Range	40 - 50	166,500	119,265	30,585	16,650	89,488	None
Dry	50 - 60	138,750	66,512	58,363	13,875	79,022	None
	60 - 70	116,550	66,512	38,383	11,655	64,389	None
	70 - 80	97,125	66,512	20,901	9,712	46,869	None
	80 - 90	80,475	66,512	5,916	8,047	53,732	None
Low Flow	90 - 100	66,600	59,940	0	6,660	26,844	None

¹ Actual Load was calculated using the 90th percentile of observed chloride concentrations in a given flow range (USEPA 2007)

2.3.3 Zinc TMDL

Thorn Creek Segment HBD-02 is listed for impairment caused by elevated zinc concentrations. Sources of zinc can include point sources and nonpoint sources. Common nonpoint sources include aging galvanized iron and steel, road salt, tire wear, and it occurs naturally bound to soils and enters streams through erosion (Schueler and Shepp 1993). Sources of zinc are also discussed in Section 3.9. A load duration curve was developed for this impaired segment (see **Section 1**) to determine load reductions needed to meet the instream chronic water quality standard of 93 µg/L zinc (dissolved) across the full range of recorded flow levels.

Table 2-25: Estimated Dissolved Zinc Loading Capacities Under Various Flow Conditions for Streams in the Thorn Creek Watershed

Estimated Mean Daily Flow (cfs)	Load Capacity (lbs/day)
5	1.74
10	3.48
50	17.4
100	34.8
500	174
1,000	348
5,000	1,740
10,000	3,480
15,000	5,230

2.3.3.1 Loading Capacity

The LC is the maximum quantity of dissolved zinc that the impaired segment can receive and still maintain compliance with the water quality standard. In order to determine the LC at various flow conditions, a range of flows were multiplied by the water quality standard (93 µg/L). **Table 2-25** contains the LCs for dissolved zinc under a range of flow conditions.

2.3.3.2 Seasonal Variation

Consideration to seasonality is inherent to load duration analysis. The dissolved zinc water quality standard is not seasonal and the full range of expected flows is represented in the LC table (**Table 2-25**). Therefore, the LC represents conditions throughout the year.

2.3.3.3 Margin of Safety

The MOS can be implicit (incorporated into the TMDL analysis through conservative assumptions), or explicit (expressed in the TMDL as a portion of the loadings), or a combination of both. An explicit MOS for the dissolved zinc TMDL of 10% was included to account for some of the limited site-specific data available within the watershed. A low rate of uncertainty in the calculations is associated with the estimated flows in the assessed segments which were based on extrapolating flows from a surrogate USGS gauge. The methodology employed in estimating watershed flows is discussed in **Section 1.5.2** of this document.

2.3.3.4 Waste Load Allocation

As with the fecal coliform TMDLs, the WLAs for dissolved zinc TMDLs apply to individually permitted facilities and MS4s that exist in the Thorn Creek watershed, as described below.

Individual NPDES permitted facilities

There are no individual NPDES permitted facilities that discharge directly to the impaired segment that have a reasonable potential for elevated zinc concentrations in their discharge. However, Aqua Illinois – University Park WWTF (IL0024473) has a permitted zinc limit, and is located approximately 13 miles upstream of the impaired segment. Hanson Material Service Yard

41 (ILG840199) is a general construction permit within the subbasin, but is unlikely to discharge elevated zinc concentrations and has no zinc permit limit.

Aqua Illinois – University Park WWTF’s design maximum flow (DMF) was used to calculate the WLA during the highest 40% of in-stream flow conditions while the facility’s design average flow (DAF) was used to calculate the WLA at lower stream flow levels (see discussion in **Section 2.3.1.5**). The use of the DMF in place of the more common DAF at higher flow conditions in the WLA calculations serves as an additional conservative measure in the TMDL calculations. This methodology essentially allows for the facility to use the entire treatment and discharge capacity available while still remaining within the WLA.

The DAFs and DMFs were multiplied by Aqua Illinois – University Park WWTF’s monthly average concentration limit for zinc of 0.079 mg/L to establish the WLA for that facility, shown in **Table 2-26**.

Table 2-26: Zinc WLAs for NPDES Permitted Point Sources in the Thorn Creek Watershed

Facility	NPDES Permit Number	Applicable Stream Segment	DAF (MGD)	WLA-DAF (lbs/Day)	DMF (MGD)	WLA-DMF (lbs/Day)
Aqua Illinois – University Park WWTF	IL0024473	HBD-06	2.43	1.60	6.44	4.2

MS4 Discharges

MS4 discharges represent runoff from municipal areas with separate stormwater sewer systems. MS4 discharges are regulated discharges and therefore, are allocated through WLAs, rather than LAs. Zinc WLAs for MS4s were calculated in a manner consistent with the calculations performed for fecal coliform TMDLs (see **section 2.3.1.4**). The total MS4 load allocations for zinc that are applied to each municipality within the impaired reach’s subbasin are shown for each applicable flow category in **Table 2-27**. It should be noted that allocations based on proportional area may not accurately reflect the distribution of various sources of pollutant loads and may need to be adjusted upon further investigation of loading from each MS4 discharge.

Table 2-27: WLA (lbs/Day) for MS4 Areas in Thorn Creek Segment HBD-02

Municipality	NPDES ID	MS4 Area in Watershed (acres)	High	Moist				Mid-Range	Dry				Low Flow
			0 - 10%	10 - 20%	20 - 30%	30 - 40%	40 - 50%	50 - 60%	60 - 70%	70 - 80%	80 - 90%	90 - 100%

Cook County Hwy Dept	ILR400485	1.8	0.005	0.002	0.0012	0.0008	0.0007	-	-	-	-	-	

2.3.3.5 Reserve Capacity

An explicit RC was not included in the TMDL calculations for zinc due to the lack of point source loading of this constituent from facilities directly impacted by changes to population or increased development within the watershed. Non-point loads of zinc are also not expected to increase as a result of the population growth anticipated for this watershed.

2.3.3.6 Load Allocation and TMDL Summary

Table 2-28 shows the summary of the zinc TMDL for segment HBD-02, along with the percent reductions required at various flow levels. This segment has one tributary point source discharge, Aqua Illinois – University Park WWTF (IL0024473) that was assigned a WLA for zinc discharges to this segment. This discharger’s permitted design average and design maximum flows were used along with the 93 µg/L permitted effluent limit to calculate the WLAs. The remainder of the WLA applied to this segment’s TMDL are related to the MS4 areas as discussed in **Section 2.3.3.4**. Under low flow and dry conditions, the calculated WLA does not include MS4s as these sources are precipitation and flow dependent.

Table 2-28: Zinc TMDL for Thorn Creek (HBD-02)

Zone	Flow Exceedance Range (%)	LC (lbs/day)	WLA (lbs/day)	LA (lbs/day)	MOS - 10% of LC (lbs/day)	Actual Load ¹ (lbs/day)	Percent Reduction Needed (%)
High	0 - 10	222	128	72	22.2	335	34%
Moist	10 - 20	89	52	28	8.9	126	30%
	20 - 30	55	33	17	5.5	63	12%
	30 - 40	40	24	12	4.0	42	6%
Mid-Range	40 - 50	31	18	10	3.1	37	16%
Dry	50 - 60	25	1.6	21	2.5	28	13%
	60 - 70	21	1.6	17	2.1	24	13%
	70 - 80	17	1.6	14	1.7	19	10%
	80 - 90	15	1.6	12	1.5	17	10%
Low Flow	90 - 100	12	1.6	9.2	1.2	14	14%

¹ Actual Load was calculated using the 90th percentile of observed zinc concentrations in a given flow range (USEPA 2007)

2.3.4 Silver TMDL

Thorn Creek Segment HBD-02 is listed for impairment caused by elevated silver concentrations. A load duration curve was developed for this impaired segment (see **Section 1**) to determine load reductions needed to meet the instream water quality standard of 5 µg/L silver (total) across the full range of recorded flow levels.

Delisting for Segment HBD-02 should be considered, since only one exceedance to the water quality standard occurred out of the 158 samples taken (see Figure 1-17).

Only one exceedance (sample collected June 5, 1987) to the water quality standard has been reported at Segment HBD-02 out of 158 samples collected (see Figure 1-17). It seems that therefore that there is insufficient indication that this segment is impaired by silver, and therefore this segment is recommended for delisting for impairment caused by silver.

2.3.5 Dissolved Oxygen in Streams

Six of the nine impaired stream segments within the Thorn Creek watershed are listed for impairment caused by low DO (Thorn Creek HBD-02, HBD-03, HBD-04 and HBD-06; North Creek HBDA-01; and Deer Creek HBDC-02). As discussed in **Section 1** of this report, a single, combined QUAL2K water quality model was developed to address the impaired segments. The combined QUAL2K model was developed to determine load reductions of oxygen-demanding materials needed to meet the 5.0 mg/L instantaneous minimum standard and the 6.0 mg/L weekly average standard (March – July).

2.3.5.1 Loading Capacity

The LC for DO impairments is the maximum amount of oxygen-demanding material that Thorn Creek segments HBD-02, HBD-03, HBD-04 and HBD-06; North Creek segment HBDA-01; and Deer Creek segment HBDC-02 can receive and still maintain compliance with the water quality

standards. Oxygen-demanding material here refers to various aggregations of NBOD (which can include organic N and ammonia), total phosphorus, CBOD, SOD, and other oxygen-demanding materials.

Sensitivity analysis performed using the QUAL2K model developed for the site showed that loads of oxygen demanding materials were the primary drivers of low DO in the Thorn Creek watershed and were the focus of subsequent model runs to identify the load reductions necessary to meet existing water quality standards. Therefore, NBOD, CBOD, and SOD are the parameters included in the TMDL calculations presented for the DO impairments in streams of the Thorn Creek watershed. The allowable loads of oxygen-demanding material, specifically NBOD, CBOD, and SOD, that can be generated in the Thorn Creek watershed and still maintain the associated water quality standards for DO were quantified using the calibrated model described in **Section 1** and are summarized in **Table 2-29** below.

Table 2-29 Modeled Loading Capacities of Oxygen Demanding Materials in Impaired Stream Segments

Contributing Oxygen Demand Parameter	LC (lbs/day)					
	HBD-02	HBD-03	HBD-04	HBD-06	HBDA-01	HBDC-02
NBOD- ammonia N	252	9.5	262	245	2	32
Total Phosphorus	10	3.8	14	7.6	1.9	8.2
CBOD	1,351	6.4	1,358	1,342	5.9	183
SOD (gO ₂ /m ² /day)	11	2	11	2	1	3.6

2.3.5.2 Seasonal Variation

Seasonality is addressed because the TMDL has been calculated during the time of year when DO will be at the lowest concentrations. This is the critical condition that represents the worst-case scenario and is therefore the most conservative way to calculate this TMDL.

2.3.5.3 Margin of Safety

The MOS can be implicit (incorporated into the TMDL analysis through conservative assumptions), or explicit (expressed in the TMDL as a portion of the loadings), or a combination of both. An explicit MOS for the DO TMDL of 10% was included to account for some of the limited site-specific data available within the watershed.

2.3.5.4 Waste Load Allocation

WLAs for DO TMDLs are applied to individually permitted facilities and MS4s that exist in the watershed, as described below.

Individual NPDES permitted facilities

Several individual NPDES permitted dischargers within the Thorn Creek watershed discharge to the segments impaired for DO. Each of these discharges and the relevant discharge concentrations were input into the existing condition QUAL2K model for calibration purposes, as described in section 1.5.1.7 of this report. WLAs are assigned to parameters for which in-stream numeric water quality standards exist. Modeling shows that the primary drivers of low DO impairments in this system are high rates of NBOD primarily as ammonia-N, CBOD, and SOD. Of these constituents, instream numeric standards currently only exist for ammonia-N and details for ammonia-N for each NPDES permit and the directly impacted segments are provided in **Table**

2-30. Two of the dischargers (Hanson Material Service Yard 41 and Village of Lynwood CCDD) are stormwater permits and do not have reasonable potential to discharge elevated concentrations of CBOD, NBOD (ammonia, nitrogen) and therefore were not assigned a WLA for this parameter.

Thorn Creek Basin Sanitary District STP and the Paradise Park MHP have permitted load limits for ammonia nitrogen (ammonia-N), which are included in **Table 2-30** and in the WLAs for the relevant impaired segment. Both facilities have permit limits for ammonia-N that vary seasonally. As the QUAL2K modeling effort focuses on the most critical period for low DO in streams of late summer, the applicable load limit for the month of August was applied for each permit. For both dischargers, a phosphorus limit of 1.0 mg/L was used as a model input, since this is the limit that has been assigned to another discharger in the watershed, Aqua Illinois – University Park WWTP; however, as there is no instream numeric water quality standard for CBOD or total phosphorus in Illinois, explicit WLA were not assigned for these parameters.

Table 2-30: Ammonia-N WLAs for NPDES Permitted Point Sources in the Thorn Creek Watershed

Facility	NPDES Permit Number	Applicable Stream Segment	Design Average Flow (MGD)	Ammonia-N WLA-DAF (lbs/day)	CBOD WLA-DAF (lbs/day)
Aqua Illinois – University Park WWTF	IL0024473	HBDC	2.43	27	n/a ¹
Mid-West Manufacturing LLC	IL0059421	HBDC-02	intermittent	n/a ²	n/a ¹

Chicago Heights Steel	IL0001678	HBDC-02	intermittent	n/a ²	n/a ¹

¹ Instream numeric water quality standard does not exist, explicit WLAs were not assigned for this parameter.

² No effluent limit for ammonia for this facility, no reasonable potential for elevated concentrations in discharge.

MS4 Discharges

MS4s represent runoff from municipal areas with separate stormwater sewer systems. MS4s contribute a significant amount of nutrients and oxygen-demanding material, including BOD, SOD and TSS. MS4s are regulated discharges and therefore, are allocated through WLAs, rather than LAs. WLAs for MS4s are calculated for parameters with numeric water quality standards by first determining the total area within a municipality's boundaries that lies within the target watershed using GIS analyses and geographic data for municipal boundaries from the U.S. Census Department (2000).

The proportion of total MS4 area to total watershed area was then calculated for each sub-watershed. This proportion was then used to migrate loads from previously calculated LAs for overland runoff to WLAs for MS4 areas during the critical annual flow condition (**Table 2-31**). This process effectively transfers MS4 load allocations for parameters with numeric water quality standards from non-regulated sources described as LAs to the WLA for regulated sources of contaminants. Segment HBD-06 is not assigned WLA for MS4s due to all available load being allocated to MOS, RC and existing permit limits for facility-based MS4s. Load reduction strategies developed for this segment will need to account for potential MS4 loads and redistribute

allocations accordingly. It should be noted that allocations based on proportional area may not accurately reflect the distribution of various sources of pollutant loads and may need to be adjusted upon further investigation of loading from each MS4 discharge.

¹ Facility-based WLA + MOS + RC accounts for the entirety of the LC for this segment, load reductions necessary.

2.3.5.5 Reserve Capacity

An explicit RC was included in the TMDL calculations for DO to account for the projected population growth in the watershed. Due to the considerable uncertainty in the impact to loads of the constituents related to DO as a result of projected changes to population or increased development within the watershed, an RC of 10% of the overall LC was selected and applied to each constituent for each impaired reach. The 10% figure roughly equates to the projected population growth within the watershed over the next 10 years (CMAP 2010).

2.3.5.6 Load Allocation and TMDL Summary

The LC for DO impairments is the maximum amount of oxygen-demanding material that a given water body can receive and still maintain compliance with the water quality standards. The allowable loads of oxygen-demanding material that can be generated in the Thorn Creek watershed and still maintain water quality standards were analyzed using the calibrated models described previously. Modeling analysis revealed that, for each of the modeled reaches in the

watershed, the DO standards could be achieved with substantial reductions in diffuse NBOD (ammonia-N) and CBOD material loads and reduced sediment oxygen demand (SOD).

The analyses indicate that, given the best available data and constructed model, low DO levels in this watershed are driven primarily by a combination of diffuse loads of oxidizing material (CBOD and ammonia-N), high SOD, and relatively low reaeration. QUAL2k modeling iterations show that total phosphorus loads have relatively minimal effect on modeled outputs of low DO in the impaired segments as oxygen-demanding materials and were subsequently not a focus of the load reduction calculations performed. Measured DO impairment, albeit based on limited data, is greatest in the upper reaches of the watershed, above all of the major point sources. It is therefore likely that the source of impairment is primarily diffuse in nature. SOD is the sum of all chemical and biological processes in the sediment that take up oxygen. SOD generally consists of a combination of biological respiration from benthic organisms and the biochemical decay processes in the top layer of deposited sediments, together with the release of oxygen-demanding (reduced) anaerobic chemicals such as iron, manganese, sulfide, and ammonia. Nutrient impairment, typical of agricultural watersheds, can result in high plant growth and decay and high SOD. In other words, SOD is generally closely linked to external loadings, whether diffuse or point

To satisfy the requirements of the TMDL analysis, incremental reductions were made in diffuse CBOD and NBOD load, sediment oxygen demand, and point source CBOD and NBOD load, as appropriate, until the relevant water quality standards were achieved. All other model parameters were maintained at baseline levels. SOD was only reduced in concert with diffuse source load reductions of equal or greater percent magnitude. This recognizes the link between SOD and external loads of nutrients and organic material from the watershed.

Potential further monitoring and implementation measures to reduce loads of oxygen demanding materials, increase aeration, and/or reduce SOD in the system are discussed in Section 3. Further monitoring is also recommended to confirm the preliminary conclusions outlined above.

Tables 2-32, 2-33, 2-34, 2-35, 2-36, and 2-37 show a summary of the DO TMDLs for Thorn Creek segments HBD-02, HBD-03, HBD-04, HBD-06, North Creek segment HBDA-01, and Deer Creek segment HBDC-02, respectively. Note that in the TMDL calculations for segment HBD-06 of Thorn Creek, the assignment of MOS and RC at 10% of the LC, combined with the facility-based WLA assigned based on existing permit limits, resulted in no allocation available for MSF-based WLA or LAs. Load reduction strategies developed for this segment should include target reductions for ammonia-N greater than the 15% minimum reduction from current loads required to meet the existing water quality standards (shown in Table 2-32) in order to allow for MOS, RC, LA, and MS4 allocation.

Table 2-32 Dissolved Oxygen (ammonia-N, phosphorus, CBOD, and SOD) TMDL for Thorn Creek Segment HBD-02

Contributing Oxygen Demand Parameter	LC (lbs/day)	WLA (lbs/day)	LA (lbs/day)	MOS (10% of LC) (lbs/day)	RC (10% of LC) (lbs/day)	Current Load (lbs/day)	Reduction Needed (lbs/day)

2.3.6 Total Phosphorus and DO TMDLs for Sauk Trail Lake

A TMDL was developed for Sauk Trail Lake to determine the pounds of total phosphorus that can be allowed as input to the lake per day and still meet the applicable water quality standard. The lowest applicable water quality standard and TMDL target for total phosphorus is 0.05 mg/L. The allowable phosphorus loads that can be generated in the watershed and still maintain water quality standards were determined with the BATHTUB model discussed in **Section 1**.

DO concentration in lakes is typically a response variable to constituents, such as phosphorus or chlorophyll "a." Chlorophyll "a" indicates presence of excessive algal or aquatic plant growth. The correlation between average DO and chlorophyll "a" is typically an inverse relationship whereas the correlation between chlorophyll "a" and average total phosphorus is typically a direct relationship. These relationships would suggest that controlling phosphorus will decrease chlorophyll "a" concentrations, which will in turn increase DO concentrations. This hypothesis is supported by Wetzel who asserts that eutrophic (nutrient-rich) lakes have rapid rates of oxygen depletion (1983). Reducing total phosphorus is likely to reduce algal growth thus resulting in attainment of the DO standard. Therefore, no direct TMDL was developed for DO, but it is assumed that implementing a total phosphorus TMDL will solve any problems with low DO.

2.3.6.1 Loading Capacity

To calculate the LC, the predictive model discussed in Section 1 was used. After the model was shown to be reasonably predictive, the observed phosphorus concentration within the model was set to the Illinois lake water quality standard, 0.05 mg/L (50 µg/L). Then, the internal and external phosphorus loadings were reduced on a percentage basis, until the predicted phosphorus concentration matched the observed phosphorus concentration of 50 µg/L. This corresponded with a percent reduction of 63% for both internal and external phosphorus loading. The total allowable load of total phosphorus into Sauk Trail Lake calculated through BATHTUB is shown in **Table 2-38**.

Table 2-38: Estimated Phosphorus Loading Capacity for Sauk Trail Lake in the Thorn Creek Watershed

Waterbody	Segment	Loading Capacity (lbs/day)
Sauk Trail Lake	RHI	3.64

2.3.6.2 Margin of Safety

The MOS can be implicit (incorporated into the TMDL analysis through conservative assumptions), explicit (expressed in the TMDL as a portion of the loadings), or a combination of both. The MOS developed for the Sauk Trail Lake TMDL is explicit. An explicit MOS of 10% was included to account for the lack of site-specific data available within this watershed. It is believed that the inclusion of an explicit MOS of 10% is adequate as the modeled values were in generally good agreement with the observed data.

2.3.6.3 Waste Load Allocation

The WLA for the phosphorus TMDL is applied to MS4s that exist in the Thorn Creek watershed, as described below. There are currently no individual NPDES permitted point sources in Sauk Trail Lake watershed.

MS4 Discharges

MS4 discharges represent runoff from municipal areas with separate stormwater sewer systems. MS4 discharges are regulated discharges and therefore, are allocated through WLAs, rather than

LAs. WLAs for MS4s in lakes are calculated in a similar way as those calculated for impaired stream segments. The total area within a municipality's boundaries that lies within the target lake's watershed was again determined using GIS analyses and geographic data for municipal boundaries from the U.S. Census Department (2000). The total municipal area within the watershed serves as an approximation of the total MS4 area in the watershed.

The proportion of total MS4 area to total watershed area was then calculated for the lake's sub-watershed. This proportion was then used to migrate loads from previously calculated LAs for overland runoff to WLAs for MS4 areas in each flow category. This process effectively transfers MS4 load allocations for

overland runoff from non-regulated sources described as LAs to the WLA for regulated sources of contaminants. The total MS4 load allocations for phosphorus that are applied to the proportion of each municipality within the impaired lake's subbasin are shown in **Table 2-39**. It should be noted that allocations based on

Table 2-39: Allocation Summary for MS4s in the Sauk Trail Lake Watershed

Source	NPDES ID	Municipal Area in Subbasin (acres)	Percent of Total Municipal Area in Subbasin	Total Phosphorus Allocation (lbs/day)
Chicago Heights	ILR400174	1.12	0.03%	0.001
Monee	ILG870335	407	9.48%	0.212
Park Forest	ILR400421	1,060	24.7%	0.553
South Chicago Heights	ILR400449	304	7.08%	0.159
University Park	ILR400250	2,471	57.6%	1.290
Illinois DOT	ILR400493	8.2	0.19%	0.004
Cook County Hwy Dept	ILR400485	23.2	0.54%	0.012
Will County	ILR400272	16.6	0.39%	0.009
Total MS4		4,291	100.00%	2.240

proportional area may not accurately reflect the distribution of various sources of pollutant loads and may need to be adjusted upon further investigation of loading from each MS4 discharge.

2.3.6.4 Reserve Capacity

An explicit RC was not included in the TMDL calculations for phosphorus due to the lack of point source loading of this constituent to Sauk Trail Lake. Non-point loads of phosphorus are also not expected to increase as a result of the population growth anticipated for the lake's watershed.

2.3.6.5 Load Allocation and TMDL Summary

A summary of the total phosphorus TMDL developed for Sauk Trail Lake is provided in **Table 2-40**. Required reductions in both internal and external total phosphorus loads are shown for the lake and reflect the reductions applied during the BATHTUB runs used to establish reduction criteria. While the overall load reduction for each segment is needed to meet the target, the relative proportion of the load reduction coming from internal or external sources can be modified and still result in compliance. Potential means of reducing both internal and external phosphorus loads into these waterbodies are discussed in detail in **Section 3** of this report.

Table 2-40: Total Phosphorus TMDL Summary for Sauk Trail Lake (RHI)

Segment	Loading Source	LC (lbs/day)	WLA (lbs/day)	LA (lbs/day)	MOS (10% of LC)	Current Load (lbs/day)	Reduction Needed (Percent)
RHI	Internal	0.05	-	0.045	0.005	0.13	63%
	External	3.59	2.24	0.99	0.36	9.68	63%
	Total	3.64	2.24	1.04	0.36	9.81	63%

2.4 LRS Allocation

Impairments based on narrative water quality standards are assessed through the development of LRSs. Watershed-specific numeric target values have been developed by Illinois EPA for LRS impairment parameters in the Thorn Creek watershed. The target values were used to develop target LCs for each impairment. The target LCs were then compared to current actual loads to develop percent reductions needed to meet the target value, as discussed in the following sections. The information provided by the development of these LRSs is intended to serve as a guide for future implementation activities to improve water quality throughout the Thorn Creek watershed.

2.4.1 LRS for TSS and Sedimentation/Siltation in Stream Segments

Thorn Creek segment HBD-02 is listed for impairment caused by TSS. Likewise, North Creek segment HBDA-01 and Deer Creek segment HBDC-02 are listed for impairment caused by excess sedimentation/siltation, a similar measure of sediment loads in a waterbody. As no numeric water quality standard exists for either TSS or sedimentation and siltation in streams in Illinois, a numeric target of 72.7 mg/L of TSS was developed by Illinois EPA for use in assessing TSS impairments. Sedimentation/siltation impairments in the Thorn Creek watershed are assessed using an LRS target value for a surrogate parameter, NVSS, of 61.6 mg/L. No TSS data exists along segment HBD-02; therefore, a load duration curve with target load capacities was developed, but no actual loads or percent reductions were included. Load duration curves were developed (see **Section 1**) for segments HBDA-01 and HBDC-02 to determine load reductions for NVSS needed to meet the instream water quality target under a full range of flow scenarios.

TSS is a measurement of the sediment and organic material that inhibits natural light from penetrating the surface water column. Excessive sediment and organic material within the water column can negatively impact fish and macroinvertebrates within the ecosystem. Excess sediment and organic material may create turbid conditions within the water column and may increase the costs of treating surface waters used for drinking water or other industrial purposes (ex. food processing). Excessive sediment can reduce spawning and rearing areas for certain fish species. Excess suspended sediment can clog the gills of fish, stress certain sensitive species by abrading their tissue, and thus reduce fish health. When in suspension, sediment can limit visibility and light penetration, which may impair foraging and predation activities by certain species.

Excessive fine sediment also may degrade aquatic habitats by altering natural flow conditions in stream environments and adding organic materials to the water column. The potential addition of fine organic materials may lead to nuisance algal blooms that may prevent a waterbody from

supporting aquatic life, aesthetic, and recreation uses. Algal decomposition depletes oxygen levels, which stresses benthic macroinvertebrates and fish. Excess algae can shade the water column and limit the distribution of aquatic vegetation. Established aquatic vegetation stabilizes bottom sediments and provides important habitat areas for healthy macroinvertebrates and fish communities.

2.4.1.1 Target Loading Capacity

The LC is the maximum TSS or NVSS load the impaired waters can receive and still meet the LRS target concentrations for TSS or sedimentation/siltation in this watershed. The allowable loads that may be generated in the watershed were determined using a range of estimated flow conditions and the numeric LRS targets of 72.7 mg/L for TSS and 61.6 mg/L of NVSS for sedimentation/siltation impairments, as discussed in **Section 1**. The TSS and NVSS LCs according to flow are presented in **Table 2-41**.

Table 2-41: TSS and Sedimentation/Siltation Loading Capacity as NVSS in Streams of the Thorn Creek Watershed

Estimated Mean Daily Flow (cfs)	TSS Target LC (lbs/day of TSS)	Sedimentation and Siltation Target LC (lbs/day of NVSS)
1	392	332
5	1,961	1,661
10	3,921	3,323
50	19,606	16,613
100	39,213	33,226
500	196,064	166,128
1,000	392,127	332,256
1,500	588,191	498,384
2,000	784,254	664,513
5,000	1,960,636	1,661,282

2.4.1.2 Percent Reduction and LRS Summary for TSS and Sedimentation/Siltation in Streams

Table 2-47 provides a summary of the LRS and TSS target LC under various flow conditions encountered from 2000 to 2016 in Thorn Creek segment HBD-02. **Tables 2-42** and **2-43** provide summaries of the LRS and percent reductions of NVSS from current conditions needed to meet the sedimentation/siltation targets under various flow conditions in North Creek segment HBDA-01 and Deer Creek segment HBDC-02.

A detailed search for TSS data collected on Thorn Creek segment HBD-02 was conducted but no data were found. As a result, the percent reduction in NVSS required to meet the LRS target value could not be calculated. Future data collection and further analysis is recommended. If the impairment is not confirmed, delisting is recommended. Implementation strategies to reduce erosion and total suspended solids in the future are presented in **Section 3**. **Table 2-42** below shows the target LC for TSS for Thorn Creek segment HBD-02.

Table 2-42: LRS Targets for TSS in Thorn Creek HBD-02

Zone	Flow Exceedance Range (%)	Target LC (lbs/day)	Actual Load (lbs/day)	Percent Reduction Needed (%)
High	0 – 10	186,674	N/A	N/A
Moist	10 – 20	74,513	N/A	N/A
	20 – 30	44,315	N/A	N/A
	30 – 40	31,766	N/A	N/A
Mid-Range	40 – 50	25,099	N/A	N/A
Dry	50 - 60	20,393	N/A	N/A
	60 - 70	17,256	N/A	N/A
	70 - 80	14,118	N/A	N/A
	80 - 90	11,765	N/A	N/A
Low Flow	90 - 100	9,412	N/A	N/A

Table 2-43 provides a summary of the LRS and percent reductions from current conditions needed to meet the NVSS target developed for sedimentation and siltation impairments under various flow conditions in segment HBDA-01 of North Creek. Data is very limited – only eight water quality samples were available, and only one exceeded the LRS target value (under moist flow conditions). Target reduction for that one exceedance was 32%. It is not possible to identify a pattern of NVSS reduction targets with such limited data. Future additional data collection is recommended and implementation strategies to reduce erosion and sedimentation/siltation in the future are presented in **Section 3**.

Table 2-43: LRS Targets for Sedimentation/Siltation in North Creek HBDA-01

Zone	Flow Exceedance Range (%)	Target LC (lbs/day of NVSS)	Actual Load (lbs/day of NVSS)	Percent Reduction Needed (%)
High	0 - 10	38,802	N/A	N/A
Moist	10 - 20	22,353	32,775	32%
	20 - 30	14,340	4,190	None
	30 - 40	7,845	N/A	N/A
Mid-Range	40 - 50	4,892	N/A	N/A
Dry	50 - 60	2,868	3,256	None
	60 - 70	1,687	N/A	N/A
	70 - 80	1,097	326	None
	80 - 90	641	535	None
Low Flow	90 - 100	186	12	None

Table 2-44 provides a summary of the LRS and percent reductions from current conditions needed to meet the NVSS target developed for sedimentation/siltation impairments under various flow conditions in segment HBDC-02 of Deer Creek. Data is very limited – only two water quality samples were available, and only one exceeded the LRS target value (under dry flow conditions). It is not possible to identify a pattern of NVSS reduction targets with such limited data. Future additional data collection and further analysis is recommended. If the impairment is not confirmed, delisting is recommended. Implementation strategies to reduce erosion and sedimentation/siltation in the future are presented in **Section 3**.

Table 2-44: LRS Targets for Sedimentation/Siltation in Deer Creek HBDC-02

Zone	Flow Exceedance Range (%)	Target LC (lbs/day of NVSS)	Actual Load (lbs/day of NVSS)	Percent Reduction Needed (%)
High	0 - 10	20,966	N/A	N/A
Moist	10 - 20	9,149	N/A	N/A
	20 - 30	5,337	N/A	N/A
	30 - 40	4,193	N/A	N/A
Mid-Range	40 - 50	3,469	N/A	N/A
Dry	50 - 60	2,783	2,647	None
	60 - 70	1,811	1,671	N/A
	70 - 80	1,220	N/A	N/A
	80 - 90	953	N/A	N/A
Low Flow	90 - 100	648	N/A	N/A

2.4.2 LRS for TSS and Sedimentation/Siltation in Sauk Trail Lake

Sauk Trail Lake is listed for impairment caused by excess TSS and sedimentation/siltation. No numeric water quality standard exists for TSS or sedimentation/siltation in lakes or reservoirs in Illinois, so watershed-specific numeric targets of 72.7 mg/L of TSS and 61.6 mg/L for the sedimentation/siltation surrogate, NVSS, were developed by Illinois EPA to aid in assessment of these impairments. A detailed search for NVSS and volatile suspended solids data collected in Sauk Trail Lake was conducted but no data were found. As a result, the percent reduction in NVSS required to meet the LRS target value could not be calculated. Future data collection is recommended and implementation strategies to reduce erosion and sedimentation/siltation in the future are presented in **Section 3**. Determination of the reduction in TSS loads needed to meet the water quality targets was performed using a simplified spreadsheet calculation approach.

Excessive TSS in lakes can negatively impact fish and macroinvertebrates within the ecosystem. Excess sediment and organic material may create turbid conditions within the water column and may increase the costs of treating surface waters used for drinking water or other industrial purposes (ex. food processing). The potential addition of fine organic materials may lead to nuisance algal blooms that may prevent a lake from supporting aquatic life, aesthetic, and recreation uses. Algal decomposition depletes oxygen levels which may further stress benthic macroinvertebrates and fish.

The spreadsheet approach incorporates the available TSS data for Sauk Trail Lake and estimates of the average daily overland and tributary flow from the watershed to produce an estimate of the current average daily TSS load into the lake. The current load is then compared to the maximum daily load possible without exceeding the watershed-specific TSS target concentration value, to calculate the overall percent reduction in daily TSS load into the lake necessary to meet the target value.

A summary of percent reduction in TSS necessary to meet the target values in Sauk Trail Lake is presented in **Table 2-45**. An overall reduction in TSS loads of approximately 6.5 percent is necessary to meet the target value in Sauk Trail Lake.

Table 2-45: LRS Summary for TSS in Sauk Trail Lake (RHI)

Segment	Target Concentration (mg/L)	Existing Concentration (mg/L) ¹	Average Overland and Tributary Flow (cfs)	Target Loading Capacity (lbs/day)	Actual Load (lbs/day)	Percent Reduction Needed (%)
RHI	72.7	77.4	12.7	4,996	5,319	6.5%

¹ Existing Concentration was calculated using the 90th percentile of observed TSS concentrations in a given location (USEPA 2007)

Section 3

Implementation Plan for the Thorn Creek Watershed

3.1 Implementation Overview

The goal of this watershed plan is to identify Best Management Practices (BMPs) that can be implemented in the Thorn Creek watershed that will provide reasonable assurance that impaired waters in the watershed will meet water quality criteria developed to ensure waterbodies are able to support their designated uses.

The USEPA has identified nine minimum elements that a watershed plan for impaired waters is required to include. A watershed plan is required to:

1. Identify causes and sources of pollution which will need to be controlled to achieve pollutant load reduction requirements estimated within the watershed plan (See Section 2.2).
2. Estimate pollutant load reductions expected as a result of implementation of the management measures described in #3 below (See Section 2.3).
3. Describe the nonpoint source management measures that will need to be implemented in order to achieve the load reduction estimates and identify the critical areas where measures need to be implemented for maximum effectiveness (See Section 3.3).
4. Identify the potential sources driving implementation of the prescribed management measures needed for project success; then determine the technical assistance needed for implementation and quantify its associated costs (See Section 3.10).
5. Include a public information/education component designed to change social behavior; then identify the indicators for success of this component (See Section 3.11).
6. Develop an implementation schedule for the plan (See Table 3-9).
7. Develop a description of interim, measurable milestones; then identify what a successful milestone looks like (See Section 3.15).
8. Identify indicators that can be used to determine whether pollutant loading reductions are being achieved over time (See Section 3.15).
9. Include the monitoring components needed to evaluate the effectiveness of the implementation efforts over time (See Section 3.15).

Element 1 has been addressed in Sections 1 and 2 of this report. The remaining elements are addressed in the following section. Additional and more detailed information on implementation

actions in the watershed can be found in the Thorn Creek Watershed Based Plan. The original plan was developed between 2003 and 2005 by the Northeastern Illinois Planning Commission (Northeastern Illinois Planning Commission 2005). In 2014, the Chicago Metropolitan Agency for Planning (CMAP) prepared an addendum to the 2005 plan (CMAP 2014).

The watershed-based plan and addendum detail specific actions required to control stormwater and reduce pollutant loading to Thorn Creek and its tributaries. The Thorn Creek Watershed Based Plan focused on addressing nonpoint source pollution and protecting and enhancing surface water quality to support designated uses, primarily in the Thorn Creek mainstem. A set of Watershed Management Recommendations (WMRs) was outlined to address the goals established by stakeholders. Effectiveness and implementation costs of a smaller set of WMRs were estimated for a subset of the WMRs and the recommendations were prioritized. The watershed-based plan addendum updated nonpoint source pollutant load estimates by land use and subwatershed and identified BMPs and watershed improvement projects to address the water quality impairments. The extent of the BMPs, estimated pollutant load reductions, and implementation costs were developed as part of the addendum. The 2005 plan can be found on CMAP's website at: <https://www.cmap.illinois.gov/documents/10180/12330/Thorn-Creek-Watershed-Based-Plan.pdf/pdf/2c37c96a-6b1a-40eb-9e10-8a8088d71690>. The plan addendum can be found at:

<https://www.cmap.illinois.gov/documents/10180/343354/ThornCreekPlanAddendumFinalCMAP-Dec2014.pdf/747d650e-808a-4858-ad5a-362f380b0968>.

The information presented in the following sections is intended to summarize implementation actions that may be utilized in the Thorn Creek watershed to improve water quality and reduce the number and degree of impairments in the watershed. More detailed information on potential actions as well as details on specific projects within the watershed can be found in the watershed-based plan and addendum.

3.2 Adaptive Management

An adaptive management, or phased approach, is recommended for the implementation of management practices designed to meet the TMDLs and LRSs developed for the Thorn Creek watershed. Adaptive management is a process for continually improving management policies and practices by learning from the in-progress results of the operational programs. Because it is driven by real-world results, adaptive management complies with the USEPA guidelines described in **Section 3.1**. Some of the defining characteristics of adaptive management include:

- Acknowledgement of uncertainty about what policy or practice is "best" for the particular management issue
- Thoughtful selection of the policies or practices to be applied to each management issue during the assessment and design stages
- Careful implementation of a plan of action designed to identify the critical knowledge needed but not available during this adaptive management phase, and to establish this missing information
- Monitoring of key response indicators

- Analysis of the management outcomes in consideration of the original objectives and incorporation of the results into future decisions (British Columbia Ministry of Forests 2000)

Implementation actions, point source controls, management measures, and/or Best Management Practices (BMPs) are used to control the generation or distribution of pollutants within a watershed. BMPs are either structural; such as wetlands, filtration basins, or filter strips; or managerial, such as land use management, effective street sweeping programs, lawn fertilizer restrictions, and public outreach or education. Both structural and managerial BMPs require effective management and maintenance to be successful in reducing pollutant loading to water resources (Osmond et al. 1995).

It is typically most effective to install a combination of point source controls and BMPs, or a BMP system. A BMP system is a combination of two or more individual BMPs that are used to control pollutants from a single critical source. If the watershed has more than one identified pollutant, but the transport mechanism is the same, then a BMP system that establishes controls for the transport mechanism can be employed (Osmond et al. 1995).

To assist in development of an adaptive management program; implementation actions, management measures, available assistance programs, and recommended continued monitoring are all discussed throughout the remainder of this section. The point source controls noted below are generally required, and are typically already being implemented, although some permit modifications may be appropriate. The nonpoint source BMPs are entirely voluntary based on stakeholder and landowner preferences.

3.3 BMP Recommendations for Reducing TSS and Sedimentation/Siltation in Streams

The following stream segments are listed as impaired for TSS and/or sedimentation/siltation: Thorn Creek HBD-02, North Creek HBDA-01, and Deer Creek HBDC-02. The watershed-specific LRS target values for TSS and sedimentation/siltation within the Thorn Creek watershed are 72.7 mg/L of TSS and 61.6 mg/L of NVSS. As discussed in **Section 2.4.2**, the segments impaired for TSS or sedimentation/siltation either had little or no data available regarding these pollutants; however, since they are listed as impaired, some management strategies are needed. **Figure 2-4** in the AECOM Stage 1 report for the Thorn Creek watershed (AECOM 2011) shows the land around the HBD-02 segment to be primarily urban and forested. The figure also shows the lands around the HBDA-01 and HBDC-02 segments to consist of urban, forested, and agricultural areas, with some of the agricultural lands immediately adjacent to portions of the impaired stream segments. Therefore, urban and agricultural BMPs are appropriate for different areas of the stream sub-watersheds.

Nonpoint source runoff from both urban and agricultural areas, decreased infiltration associated with the prevalence of impervious surfaces, and increased overland flow are the main contributors to high sediment loads in the Thorn Creek watershed. Most modern developments route runoff from impervious surfaces directly into storm sewers or paved channels which effectively convey the pollutants, including sediments and suspended solids, into receiving waterbodies with little to no opportunity for infiltration or filtering. The storm sewers and lined

channels then convey the runoff water downstream at a much faster rate than would normally occur in a natural, non-urbanized, setting. The increased flow rate leads to several issues including stream channel erosion and/or downcutting of the channel, both of which contribute to sedimentation/siltation and suspended solid loads. Alterations to natural storage and conveyance functions (e.g., stream channel modification) can also result in increased flow velocities and volumes subsequently causing stream channel erosion and increased flooding.

In addition to flow and conveyance concerns, building and road construction activity in and adjacent to waterbodies and wetlands create both short-term and long-term effects on water quality. Although erosion on construction sites often affects only a relatively small acreage of land in a watershed, it is a major source of sediment because the potential for erosion on highly disturbed land is commonly 100 times greater than on agricultural land (Brady and Weil 1999). The primary short-term effect is erosion in the denuded areas, those lacking vegetation, with potential deposition of sediment in nearby waterbodies. The long-term effects of urban development upon waterbodies and wetlands primarily result in the elimination of vegetation and other natural materials. The typical consequences of these alterations include reduced shading and a resultant increase in water temperature, reduced capacity for pollutant filtering, and increased stream instability and erosion.

Given these factors, nonpoint source controls designed to control erosion sources and/or to reduce TSS and NVSS loads stemming from overland flows in urban areas (discussed below) have been shown to reduce the TSS and sedimentation/siltation issues present in streams and lakes/reservoirs as well as provide a secondary benefit of reducing other contaminants, such as excess nutrients, that may be entering waterways via erosive processes. The BMPs discussed below are applicable to TSS and/or sedimentation/siltation impairments within the listed watersheds, and many of the BMPs may be used in both urban and agricultural settings. Applicable BMPs are also discussed in Section 4 of the 2014 watershed-based plan Addendum.

Urban BMPs:

- Grass Filter strips
- Urban Reforestation/Forested Riparian Buffer Restoration
- Wetlands
- Stormwater Retention Basins (dry and wet ponds)
- Vegetated Swales
- Permeable Pavement
- Sand Filters
- Compost Blankets, Filter Berms, and Filter Socks
- Stormwater Reduction Techniques
- Bio-Retention Cells

- Streambank Stabilization and Erosion Control
- Street Sweeping

Agricultural BMPs:

- Grass Filter Strips
- Wetlands
- Compost Blankets, Filter Berms, and Filter Socks
- Streambank Stabilization and Erosion Control
- Conservation Tillage Practices

Grass Filter Strips: Filter strips are applicable to both rural and urban settings. Filter strips are vegetated areas of land planted along waterways (typically with grading efforts designed to reduce inflow rates) that are used to intercept runoff before it can enter a waterbody. The vegetation in the filter strip slows and filters runoff thereby serving as a control to reduce both pollutant loads from runoff and sedimentation to the impaired waterbody. Filter strips also provide bank stabilization thereby decreasing erosion and re-sedimentation. Grass filter strips have been shown to remove as much as 65 percent of

Schematic of a filter strip and illustration of its benefits (USEPA 2017).

sediment and 75 percent of total phosphorus loads from runoff (USEPA 2003). For agricultural areas, the Illinois Natural Resources Conservation Service (NRCS) Conservation Practice Standard 393 (June 2003) describes filter strip requirements based on land slope; the requirements are designed to achieve a minimum flow through time of 15 to 30 minutes at a one-half inch depth. **Table 3-1** provides a summary of the guidance for filter strip width, or flow length, as a function of slope (NRCS 2003). For more urbanized areas, the NRCS document *Urban Soil Erosion and Sedimentation Control* (NRCS 2008), suggests that filter strips are most effective in filtering runoff when slopes are less than 5%, but will function with a maximum slope of up to 15%.

Table 3-1: Filter Strip Flow Lengths Based on Land Slope

Percent Slope	0.5%	1.0%	2.0%	3.0%	4.0%	5.0% or greater
Minimum (feet)	36	54	72	90	108	117
Maximum (feet)	72	108	144	180	216	234

GIS land use data were used to provide an estimate of acreage within the Thorn Creek watershed where filter strips could be installed. In conjunction with the available land use, topography, and soil information discussed in the Stage 1 report, mapping software was used to identify potential buffer areas for impaired stream segments to an appropriate and reasonable width, described in **Table 3-1** above, to determine the total area found in each subbasin. Due to the diversity of soil types and slopes found throughout the watershed, the appropriate buffer widths estimated in GIS

were based on the average slope of land within the maximum buffer areas of each impaired segment. These average slopes were then used to calculate approximate buffer distances based on the NRCS guidance using Table 3-1.

Not all land use types within the buffer areas are candidates for conversion to buffer strips. Existing forests and wetlands already function as filter strips or riparian buffers and conversion of developed residential or commercial lands is often infeasible. Because the primary land use within the buffer zones is urban, the greatest benefit to water quality may be installation of filter strips where there are semi-developed pervious land areas, e.g., parks or open areas within the stream buffers. Therefore, GIS software was used to calculate the approximate acreage of all non-forested lands within the appropriate buffer area for each impaired stream segment and its tributaries. These calculated buffer areas and acreage of convertible land within the buffer distances for each impaired stream segment and its tributaries are provided in **Table 3-2**. These data represent an approximation of the maximum acreage of land potentially available for conversion to filter strips along the mainstem of the impaired streams. More detailed assessment of a given property is necessary to determine the exact size and extent of convertible lands likely to provide the greatest benefit to instream water quality following conversion to filter strips.

There are approximately 992 total acres within the various buffer distances of impaired stream segments, an estimated 442 acres of which are not currently forest, wetland, or undeveloped grassland and where filter strips could be installed to benefit water quality. Much of the remaining land is currently low and medium density developed land which will need to be evaluated on a parcel-by-parcel basis to determine the feasibility of potentially installing this type of BMP. Landowners or managers should be encouraged to evaluate their land adjacent to impaired streams and their tributaries to determine the practicality of installing or extending filter strips to achieve effective flow lengths as described in the NRCS guidance provided in **Table 3-1**. Figures depicting the buffered areas and/or agricultural and urban lands suitable for conversion to filter strips in each subbasin are provided as **Figures 3-1** through **3-3**. Note that the land areas shown in red are unsuitable for conversion to filter strips. Table 3-2 Average Slopes, Filter Strip Flow Length, Total Buffer Area, and Area of Land within Buffers Potentially Suitable for Conversion to Filter Strips, by Stream Segment

Table 3-2: Average Slopes, Filter Strip Flow Length, Total Buffer Area, and Area of Land within Buffers Potentially Suitable for Conversion to Filter Strips, by Stream Segment.

Stream Name	Segment ID	Average Slope Adjacent to Streams (%)	Filter Strip Flow Length (feet)	Total Area in Buffer (Acres)	Potentially Convertible Land in Buffer (Acres)
Thorn Creek	HBD-02	5	234	218.65	45.73
North Creek	HBDA-01	2	144	430.69	231.74
Deer Creek	HBDC-02	2	144	342.25	164.44

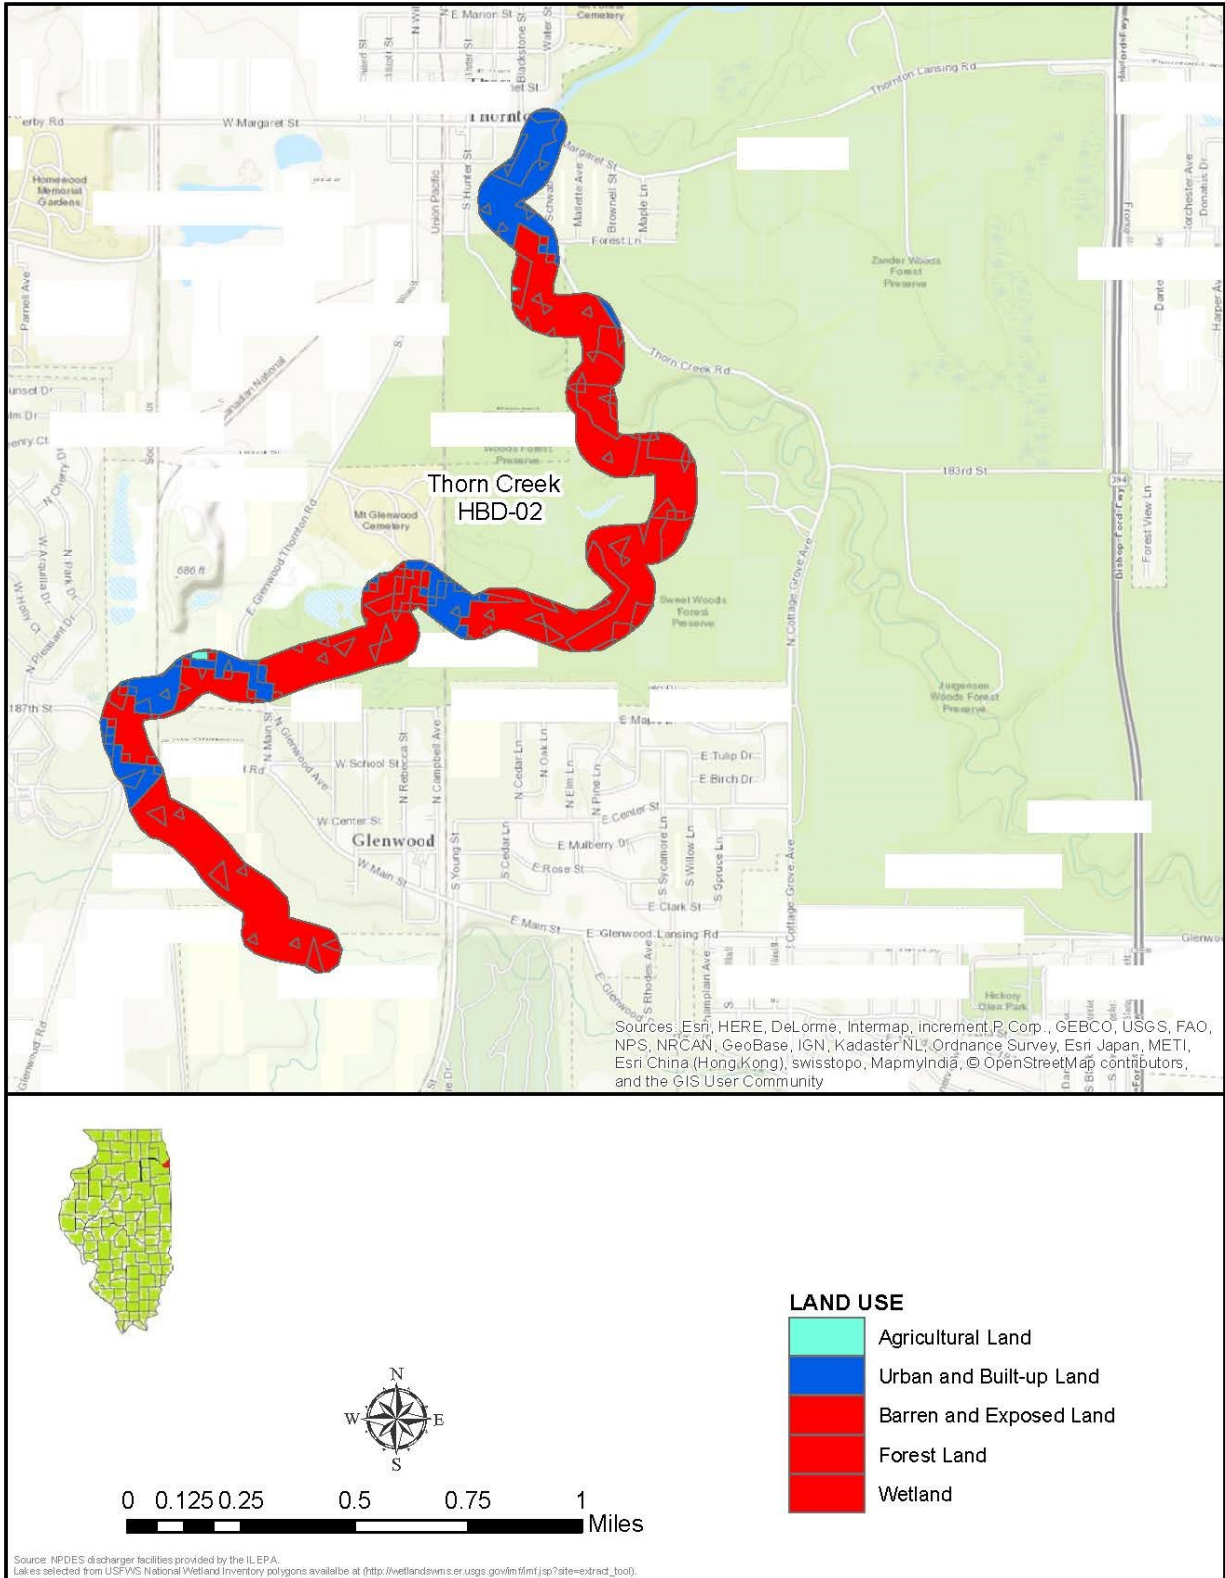

Figure 3-1: Thorn Creek Segment HBD-02 Buffer Land Uses Suitable for Conversion to Filter Strips

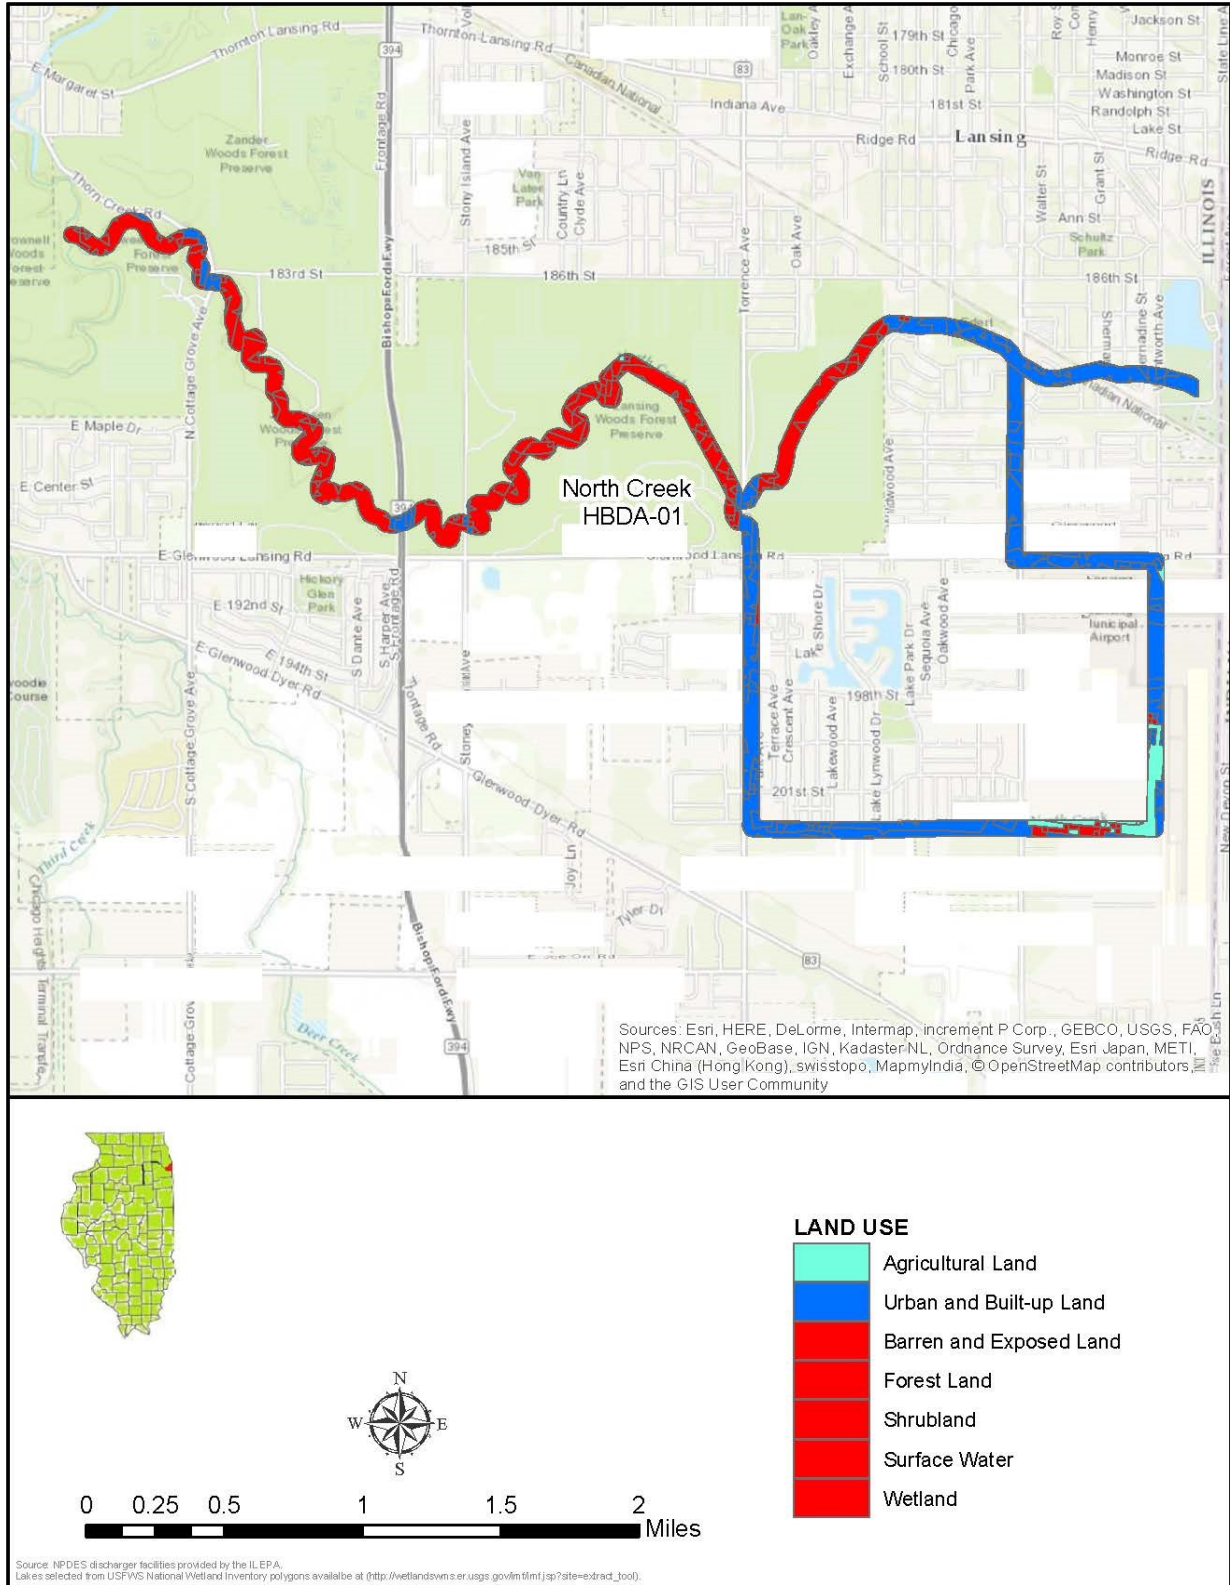

Figure 3-2: North Creek Segment HBDA-01 Buffer Land Uses Suitable for Conversion to Filter Strips

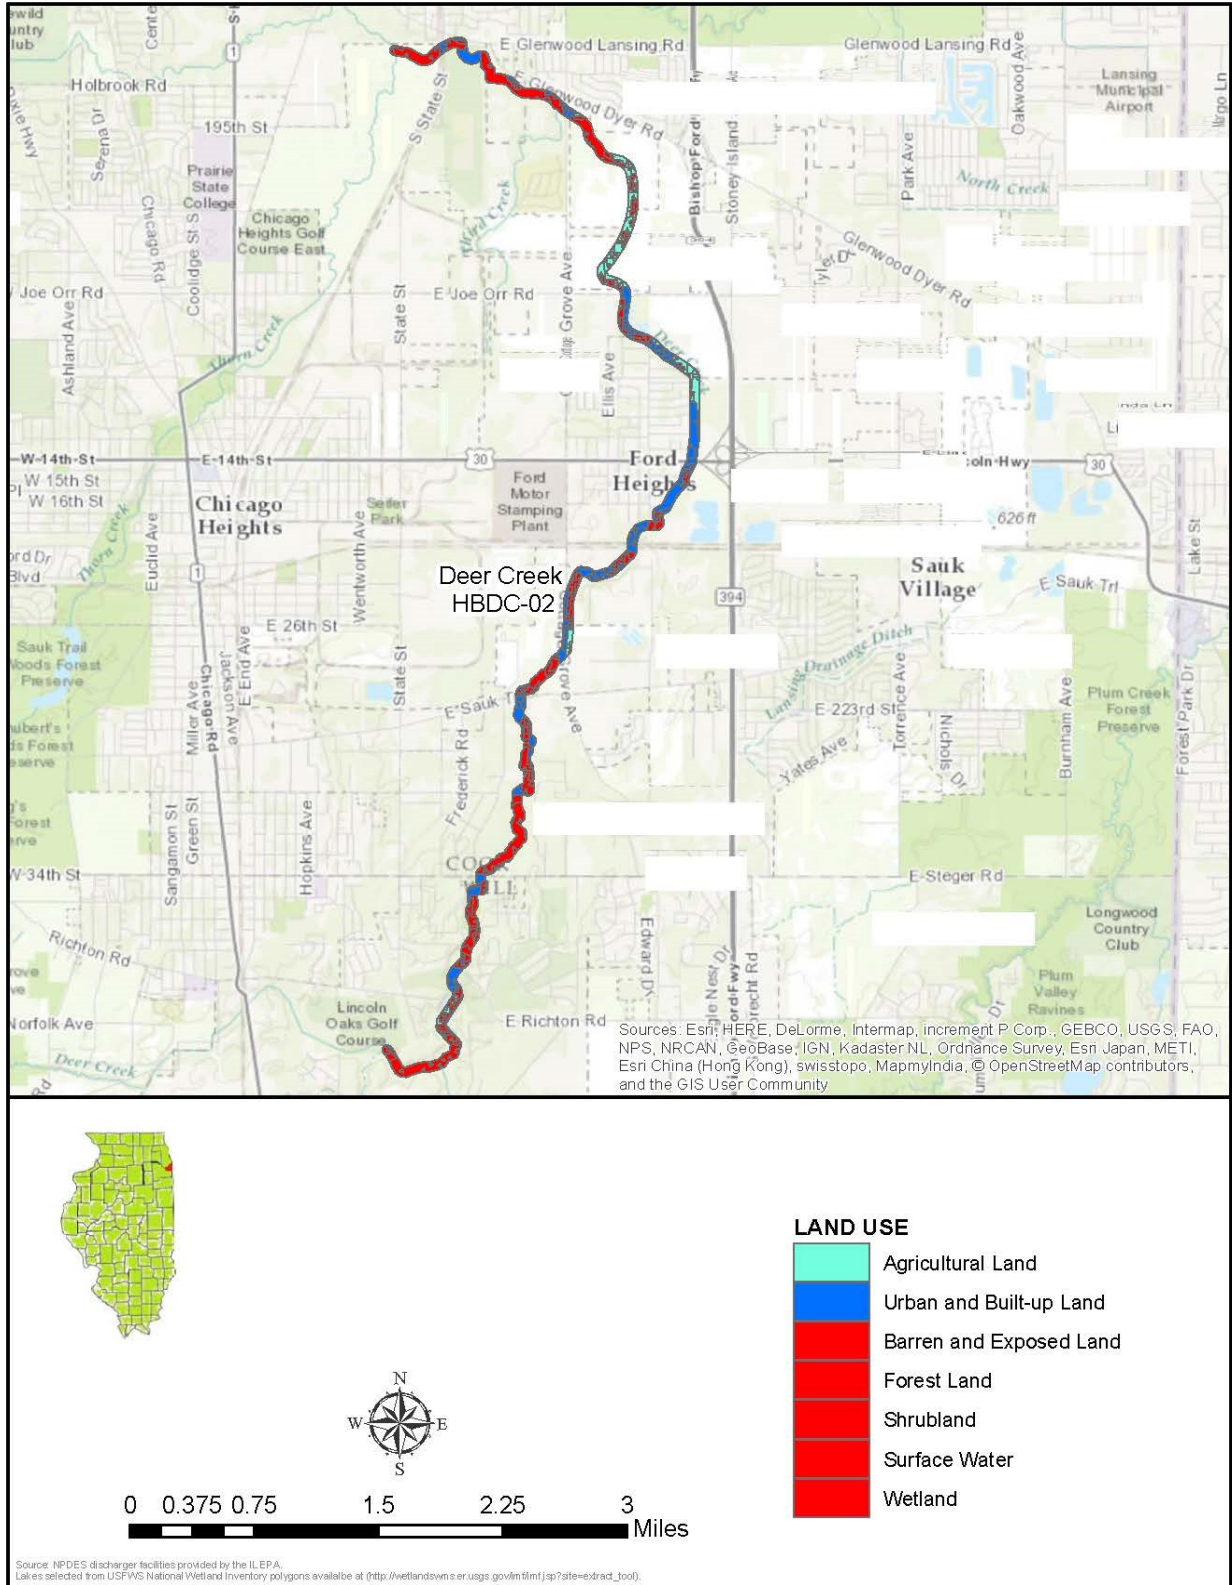

Figure 3-3: Deer Creek Segment HBDC-02 Buffer Land Uses Suitable for Conversion to Filter Strips

Urban Reforestation/Forested Riparian Buffer Restoration: Riparian buffers are also applicable to both rural and urban settings. Urban reforestation is the practice of planning and planting large areas of trees to increase the urban canopy and decrease impervious area. Riparian buffers are vegetated areas of land used to intercept runoff before it can enter a waterbody. The buffers slow and filter runoff thereby serving as controls to reduce both pollutant loads from runoff and sedimentation to the impaired waterbody. Maintaining and/or restoring riparian buffers with trees helps to filter pollutants out of runoff from roads, parking lots, and other paved areas. The trees provide shade to moderate soil and stream temperatures, which helps maintain healthy dissolved oxygen levels for aquatic life. Additionally, the rooting systems of the vegetation serve as reinforcements in streambank soils, which help to hold streambank material in place and minimize erosion. Due to the increase in stormwater runoff volume and peak rates of runoff associated with urban development, stream channels are subject to greater erosional forces during stormflow events. Preserving natural vegetation along stream channels therefore

*Forested riparian buffer (D*Hub 2016)*

minimizes the potential for water quality and habitat degradation due to streambank erosion as well as that additional pollutant or sediment load entering the stream.

The USEPA (2003) reports phosphorus removal rates of approximately 25 to 30 percent for 30 foot wide buffers and 70 to 80 percent for 60 to 90 foot wide buffers. Riparian corridors can typically treat a maximum of 300 feet of adjacent land before runoff forms small channels that short circuit treatment. Land use data for the

Thorn Creek watershed were clipped to 25 feet buffer zones created around the impaired stream segments. Existing grassland, forest, and agricultural areas within the 25-foot buffer zones are shown in **Table 3-3** by segment. Landowners should assess parcels adjacent to the stream channels and maintain or improve existing riparian areas or potentially convert cultivated lands.

Table 3-3: Total Area and Area of Grassland, Forest, and Agricultural Land within 25-Foot Buffer, by Stream Segment

Stream Name	Segment ID	Area in 25 ft Buffer (Acres)	Grassland in 25 ft Buffer (Acres)	Forest in 25 ft Buffer (Acres)	Agricultural Land in 25 ft Buffer (Acres)
Thorn Creek	HBD-02	31.02	0	8.04	0
North Creek	HBDA-01	98.44	0.33	10.81	3.80
Deer Creek	HBDC-02	77.51	0.34	20.56	8.23

Implementation of an urban reforestation/riparian buffer restoration program requires a coordinated effort and sites should be prioritized for best results. The Northern Virginia BMP Handbook (1997) suggests the following considerations:

- Is the land already owned or planned for a public or semi-public use? In general, obtaining permission to replant a denuded buffer within an existing or planned public land use is more feasible than obtaining permission to replant on private land.

- Is the land slated for future development or infrastructure or has a riparian reforestation project already been planned for the site? It is best to consult with other agencies and organizations to be sure that there is no duplication of plans and to ensure that what is planted is not in an area slated for future development or the infrastructure that accompanies development. This includes communication with adjacent property owners and all utility companies (sewer, electric, cable, and phone).
- Does the site build upon already existing buffer areas to create a more robust forested buffer system? If a vegetated buffer is already in place, obtaining permission from a private landowner, or going through proper regulatory channels if the buffer is located on public land, may be more simple than attempting to convert a land use type to establish a forested buffer.
- Does the stream reach contain sensitive or endangered natural resources that will benefit from riparian reforestation? If a stream reach has been identified as being critical habitat to an endangered species, reforestation of that stream reach may be a priority.
- Will a buffer area reduce nonpoint source pollution from adjacent land uses or will adjacent land uses serve to degrade the buffer area? Buffer areas are effective at controlling pollutants in runoff only when the stormwater enters the system as slow, overland sheetflow. Buffer areas abutting large lot residential areas, or institutions with large areas of grass, can serve to significantly reduce nonpoint source pollution. However, buffers may not be useful, and may be damaged, if located near highly impervious land cover without adequate safeguards.
- Do the physical conditions of the site (such as degraded or under-cut streambanks or physical structures) allow the possibility of a vegetated buffer; and would additional site engineering be required? If so, would the cost, in terms of money and potential short term physical degradation, be worth the long term benefits?

Once program goals and objectives have been determined and sites have been prioritized, the Northern Virginia BMP Handbook also suggests the following to aid in the success of the program:

- Determine Planting Purposes – While the purpose of this suggested program is the reduction in nonpoint source pollution (particularly TSS through control of soil erosion, but also nutrients and oxygen demanding materials – to be discussed later in this section) other goals and objectives may coincide and be complimentary to nonpoint source pollution reduction. These other purposes may include: shade (temperature control and habitat); shelter from winds; screening of unsightly views; privacy buffers; boundaries for traffic control; lowering of carbon dioxide levels; reduced energy costs for buildings; specimen landscaping features and the removal of invasive plants; and potentially increased property values.
- Determine the General Planting Location Based on Objectives – Once the purpose has been established, where to plant should be considered to fulfil these purposes. As discussed above, urban reforestation/riparian buffer restoration should be focused in areas that are beneficial to the impaired stream segments in this watershed. Additional consideration in

the placement of trees is the location of underground utilities. Location of underground utilities should be the first step in determining plant placement.

- **Determine Ownership and Get Permission to Plant**– If the planting is to be done on private property, the ownership of that property must be established and permission granted to go forth with the project. One must also receive permission to plant in public areas, whether it is a school, library, park, etc. Care should be taken not to plant in a public easement such as a future street right-of-way, sanitary sewer, or stormwater detention facility without proper permission. Trees may be removed or end up being damaged otherwise. Riparian buffer restoration work may require additional approvals. For instance, it is always wise to notify the Army Corps of Engineers about project activities. It is possible that the project will require a permit because the stream flow is being temporarily disturbed.

In addition to all of the above considerations, it is suggested that any program to reforest or restore riparian buffers should consult with a local arborist and/or area nurseries to determine the best trees for the available space, local climate, and soil types.

Wetlands: The use of wetlands as a structural control is applicable to sediment and nutrient reduction from urbanization in the Thorn Creek watershed. Even in urban settings, wetlands serve as an important buffer between terrestrial activities and aquatic environments. Existing wetlands should be maintained and additional wetlands could be constructed to treat loads from runoff at select locations where more focused runoff occurs and land use allows; e.g., at the

Wetlands (Oklahoma Conservation Commission 2015)

downstream end of a drainage channel. Wetlands are effective BMPs for nutrients and sediment control because they filter sediment and slow overland flow, thereby reducing soil erosion (NRCS 2014).

A properly designed and functioning wetland can provide very efficient treatment through nutrient cycling. Design of wetland systems is critical to the sustainable functionality of the

system and should consider soils in the proposed location, hydraulic retention time, and space requirements. In general, soils classified as hydric are most suitable for wetland construction. The current extent of soils classified as hydric by the NRCS as well the current extent of existing U.S. Fish and Wildlife classified wetlands in the Thorn Creek watershed are shown in **Figure 3-4** and **Figure 3-5**. Areas near waterways that are not currently classified as wetlands but have hydric soils present are typically strong candidates for potential wetland construction. Existing wetland areas may also be candidates for reconstruction or enhancement to improve their nutrient uptake capacity. These data layers are developed on a large-scale and onsite soil investigation and wetland delineation is typically necessary for verification of the suitability of a given area for wetland construction.

Constructed wetlands, which comprise the second or third stage of a nonpoint source treatment system, can be very effective at improving water quality. Studies have shown that artificial

wetlands designed and constructed specifically to remove pollutants from surface water runoff have removal rates of greater than 90 percent for suspended solids, up to 90 percent for total phosphorus, 20 to 80 percent of orthophosphate, and 10 to 75 percent for nitrogen species (Johnson, Evans, and Bass 1996; Moore 1993; USEPA 2003; Kovosic et al. 2000). Although the removal rate for phosphorus is low in long-term studies, the rate can be improved if sheet flow is maintained to the wetland and vegetation and substrate are monitored to ensure the wetland is operating optimally. Sediment or vegetation removal may be necessary if the wetland removal efficiency is lessened over time (USEPA 2003). Guidelines for wetland design suggest a wetland to watershed ratio of 0.6 percent for nutrient and sediment removal from agricultural runoff.

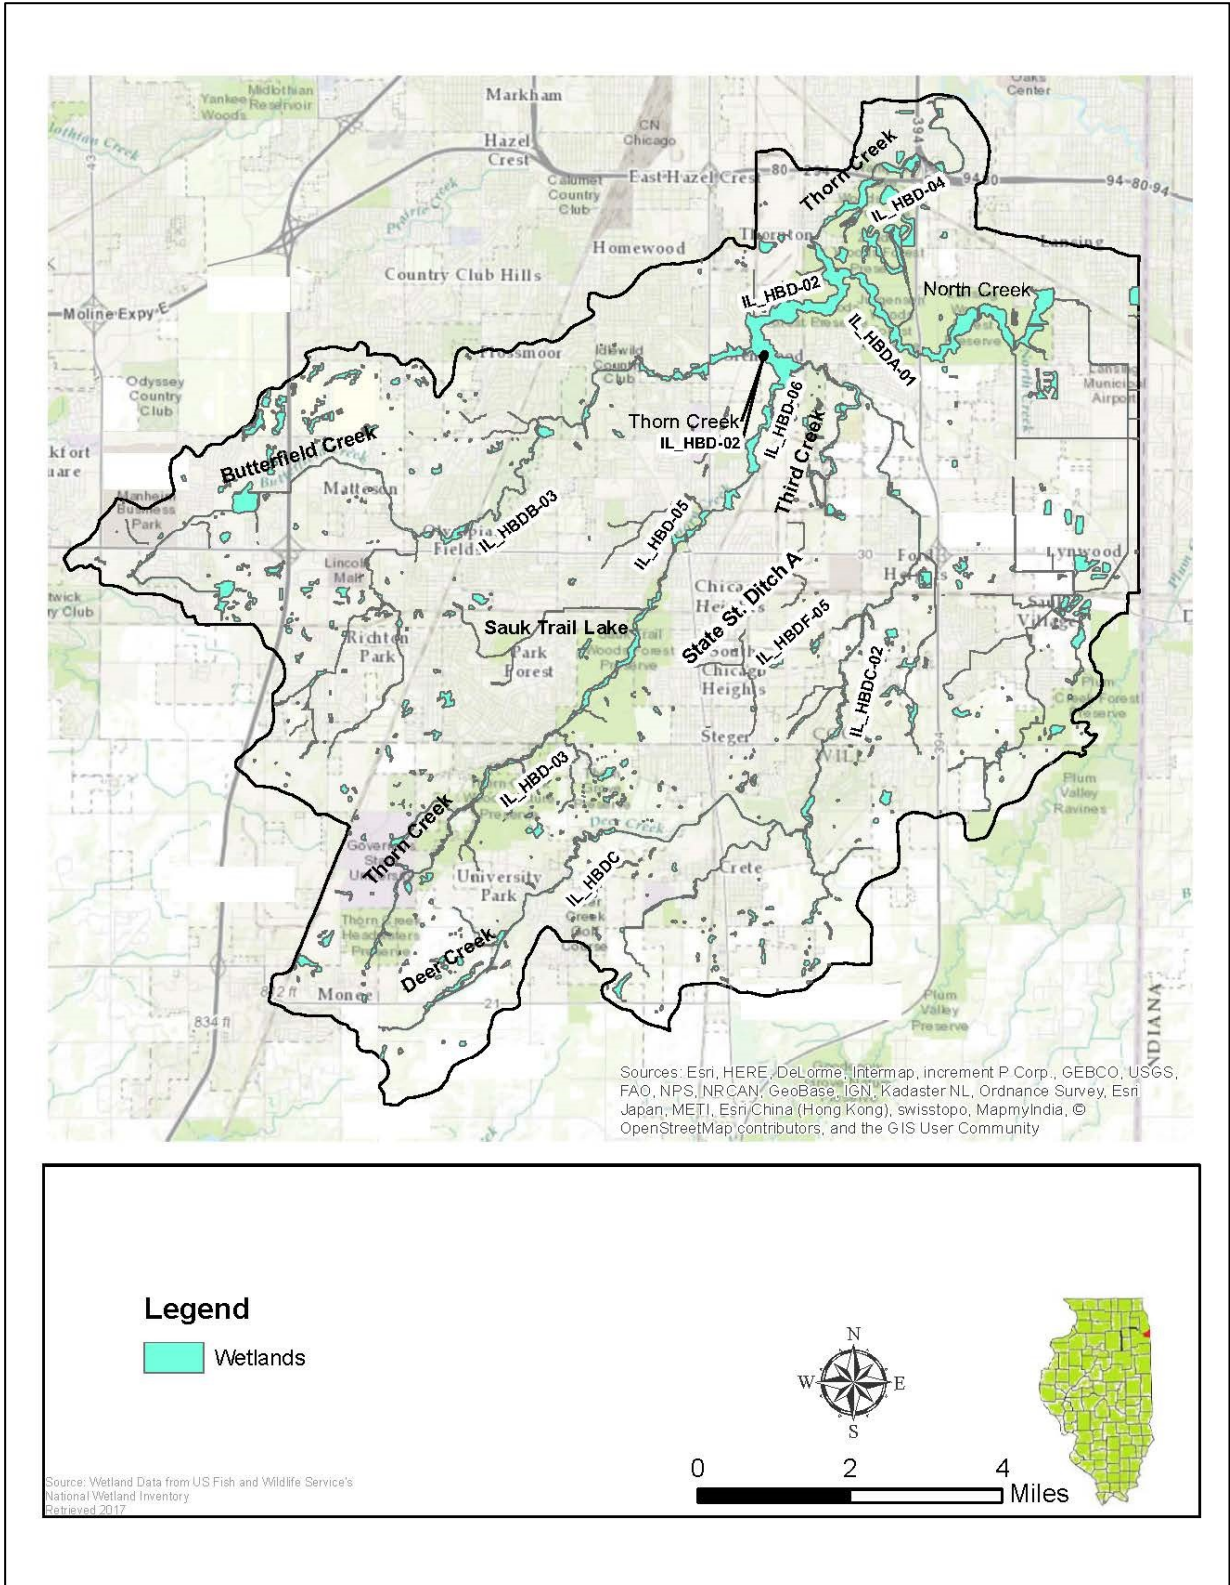

Figure 3-5: Thorn Creek Watershed Wetlands

Stormwater Retention Basins (Dry and/or Wet Ponds): Control basins and ponds (“dry” or “wet”) may be used for flood control and treatment of stormwater. Both systems function to settle suspended sediments and other solids typically present in stormwater runoff.

Stormwater ponds are also called retention ponds or “wet” ponds and they hold back water similar to water behind a dam. The pond has a permanent pool of water that fluctuates in response to precipitation and runoff from the contributing areas. Maintaining a pool discourages resuspension and keeps deposited sediments at the bottom of the holding area. USEPA’s 1993 Nationwide Urban Runoff Program indicated that up to two-thirds of the sediment, some nutrients and trace metals can be removed via sedimentation within 24 hours, while two weeks are required to remove a significant amount of phosphorus. A wet detention basin must receive and retain enough water from rain, runoff, and groundwater to maintain a permanent pool in the deeper areas of the basin. Most sources recommend a minimum drainage area of 10 to 25 acres to sustain a constant inflow. Wet detention basins should be sized to treat the water quality volume and detain and release the 100-year event. The permeability of hydrologic soil groups “C” and “D” is suitable for a wet basin without modification. The side slopes of a wet detention basin should be no steeper than 5:1 above the normal water level (DuPage County 2008).

Stormwater retention basin (USEPA 2016a)

Dry ponds which may also be referred to as extended detention basins, detention ponds, and/or extended detention ponds are basins whose outlets are designed to detain the stormwater runoff from a water quality “storm” for some minimum duration (e.g., 24 hours) which allow sediment particles and associated pollutants to settle out. Unlike wet ponds, dry extended detention ponds do not have a permanent pool. However, dry extended detention ponds are often designed with small pools at the inlet and outlet of the pond, and can also be used to provide flood control by including additional detention storage above the extended detention level.

Although the Thorn Creek watershed is highly urbanized, both wet and dry ponds can be very useful stormwater retrofits with two primary applications as a retrofit design. In many communities, including the Chicago metropolitan area, detention basins have been designed for flood control in the past. It is possible to modify these basins to incorporate features that encourage water quality control, and/or channel protection. It is also possible to construct new dry extended detention ponds in open areas of a watershed to capture existing drainage, or create them above a road crossing or culvert.

In general, dry extended detention ponds should be used at sites with a minimum drainage area of 10 acres. On smaller sites, it may be difficult to provide channel or water quality control because the orifice diameter at the outlet becomes very small, and is thus prone to clogging. In addition, it is generally more cost-effective to control larger drainage areas due to the economies

of scale in pond construction. Dry ponds can be used on sites with slopes up to about 15% although the local slope needs to be relatively flat to maintain reasonably flat side slopes. While there is no minimum slope requirement, enough elevation drop is needed from the pond inlet to the pond outlet to ensure that flow can move through the system (Stormwater Manager's Resource Center 2016).

Vegetated Swales: Vegetated swales are an effective infiltration-based technique in an urban setting. These swales use an open channel designed to attenuate runoff. As runoff or stormwater discharge enters these channels, it is slowed by the vegetation; this subsequently reduces sediment suspension, promotes filtration through soil, and increases infiltration into groundwater. Pollutants are removed by settling and infiltration into soil and by biological uptake of nutrients. They also increase the time of retention within the watershed, further reducing peak flow rates. Grassed swales therefore provide the benefits of reducing peak flows and increasing pollutant removal, at low capital cost. Swales are particularly well suited for highways, roads, and parking lots because the channel designs are straight and can be easily incorporated into design schemes (Koski and Kinzelman 2010). Swales are not practicable in areas with flat grades, steep grades, or in wet or poorly drained soils, but are an excellent choice for many urban areas given the low land area requirements compared to many alternatives.

The swales can be used as a standalone option or as a conveyance mechanism to channel runoff to other retentive BMPs. Benefits of this BMP come from reductions in runoff volume and removal of nutrients, sediments, and heavy metals [TSS (86%), total phosphorous (34%), soluble phosphorous (38%), total nitrogen (84%), carbon (69%), and moderate reductions of heavy metals (cadmium 42%, copper 51%, lead 67%, and zinc 71%)] (Schueler and Holland 2000b).

Vegetated swales (Dott Architecture 2010)

Permeable Pavement: Permeable pavement removes waterborne pollutants from stormwater runoff and allows it to filter through the underlying soil. Permeable pavements functions similar to other infiltration measures. The pavement traps some particulate bound pollutants, but most of the runoff and pollutants are discharged to the groundwater, as there is usually little organic-rich soil beneath permeable pavements that trap the pollutants as in most other infiltration devices.

Permeable pavement (NCSWCD 2017)

A permeable pavement is constructed of a permeable asphalt or bituminous concrete surface with a 2.5 to 4 inch thickness that is placed over a highly permeable layer of crushed stone or gravel, 24 inches thick. A filter fabric can be placed beneath the gravel or stone

layer to prevent movement of fines into the deeper layers, although many installations show clogging of the filter fabric, and most recent designs use rock filters and not filter fabrics. Runoff from the stone and gravel layers then infiltrates into the soil. If the infiltration rate is slow, perforated underdrain pipes can be placed in the stone layer to convey the water back to a surface waterway. The primary advantage of permeable pavement is that it can be put to dual use, allowing the mitigation of waterborne pollutants, while still allowing urban use of the land, i.e. driving. But, permeable pavements are not as durable as conventional pavements and generally have much lower vehicle load limits. Also, they are costlier than conventional pavements (Pitt and Narayanan 2016), and require regular street sweeping to maintain their ability to infiltrate water.

Sand Filters. Sand filters are also an infiltration-based technique that can be used for both sediment/TSS and pollutants. Water enters a settling basin to remove heavier sediments and is then directed to filter media composed of sand or an appropriate organic material. Sand filters are a good option for highly urban areas because they occupy little space, tend to be easier to retro-fit compared to other BMPs, and have few design restrictions. However, these types of structures can be high maintenance and costly to construct (USEPA 1999). Sand filters can

Sand filter (DEP 2017)

effectively remove a large range of pollutants, including the following: fecal coliform from 51% to over excess of 99% (Schueler and Holland 2000a, Clary et al. 2008), TSS at an average of 87% (Schueler and Holland 2000b), total phosphorus at around 59%, and carbon at about 67%.

Compost Blankets, Filter Berms, and Filter Socks: Compost blankets, compost filter berms, and compost filter socks are BMPs employed to reduce surface runoff,

particularly addressing the reduction of sediments and other suspended solids.

- Compost blanket: This is a layer of loosely applied composted material placed on soil in a disturbed area to reduce stormwater runoff and erosion. The material fills in small rills and voids to limit channelized flow, provides a more permeable surface to facilitate stormwater infiltration, and promotes revegetation. Seeds can be mixed into the compost before it is applied. Applying a compost blanket works well as a stormwater BMP because it a) retains a large volume of water, which aids in establishing vegetation growth within the blanket, b) acts as a cushion to absorb the impact energy of rainfall, which reduces erosion, c) stimulates microbial activity that increases the decomposition of organic matter, which increases nutrient availability and improves the soil structure, d) provides a suitable microclimate with the available nutrients for seed germination and plant growth, and e) removes pollutants such as heavy metals, nitrogen, phosphorus, fuels, grease, and oil from

Compost filter berm (UGA Extension 2012)

stormwater runoff, thus improving downstream water quality (USEPA 1998).

- **Compost filter berm:** A compost filter berm is a dike of compost or a compost product that is placed perpendicular to runoff to control erosion in disturbed areas and retain sediment. Compost berms can be placed at regular intervals to help reduce the formation of rill and gully erosion when a compost blanket is stabilizing a slope.
- **Compost filter sock:** A compost filter sock is a three-dimensional tubular sediment control and stormwater runoff filtration device typically used for perimeter control of sediment and soluble pollutants (such as phosphorus and petroleum hydrocarbons). They are effective when installed perpendicular to sheet or low concentrated flow. Compost filter socks trap sediment and soluble pollutants by filtering runoff water as it passes through the matrix of the sock and by allowing water to temporarily pond behind the sock, allowing deposition of suspended solids. Applications include: construction sites; site perimeters; above and below disturbed areas subject to sheet and rill erosion; above and below exposed and erodible slopes; along the toe of stream and channel banks; around area drains or inlets located in a 'sump'; and on or around areas where trenching of silt fence is difficult or impossible, such as on compacted soils, frozen or paved ground, or around sensitive trees where trenching of silt fence is not beneficial for tree survival or may unnecessarily disturb established vegetation.

Stormwater Reduction Techniques: Reducing the amount of stormwater entering receiving waterbodies via overland flow can help reduce the amount of sediment and pollutants concurrently carried into the waterbodies. Stormwater reduction techniques which may be implemented in urban settings include the following:

- **Rain barrels:** These are designed to catch water from downspouts and store it for non-potable uses such as gardening.
- **Rain gardens** are a type of bio-retention cell (which are described below)
- **Green roofs:** These are an engineering technique that uses vegetation on rooftops to reduce runoff, which in turn reduces the transport of sediment. In urban areas, green roofs can represent a large surface area, and may help retain as much as 87% of rainfall.

Bio-retention cells: Bio-retention cells, or rain gardens, are a low impact development technique in which vegetation and infiltration are used to hold and treat stormwater at the source of discharge. Properly used bio-retention cells can reduce runoff volumes, increase groundwater recharge, increase evapotranspiration, provide a lag time for discharged runoff, and reduce pollutants entering ground and surface waters (Hunt et al. 2008). The cells were initially designed to handle the runoff

Bio-retention cell (CU 2015)

from smaller sites, between one and three acres, but can be modified to fit inside a variety of sites.

Bio-retention cells are designed to decrease the volume of effluent as well as improve water quality through filtration, infiltration, adsorption, and bio-transformations. Typical designs consist of sloped grass buffer strips which convey water into an infiltration basin. The infiltration basin consists of a layer of highly permeable media, such as sand, which is covered by a layer of planting soil and mulch. The mulch layer is planted with fauna such as earthworms to keep soil pores open, increase transpiration, and potentially uptake pollutants. Depending on the soil infiltration rate of the site, an underlying drain can be added to remove excess water from the media. In bench studies of simulated bio-retention cells, fecal coliform reduction rates have been observed from 54 to 99.8% with an average decrease of 91.6% (Rusciano and Obropte 2007); copper, lead and zinc were removed in excess of 95%; and total phosphorus was removed at approximately 80% (Koski and Kinzelman 2010).

Streambank Stabilization/Erosion Control: Soil erosion is the process of moving soil particles or sediment by flowing water or wind. Additionally, eroding soil transports pollutants that can potentially degrade water quality. Three available approaches to potentially decrease nonpoint TSS, sedimentation/siltation, and/or pollutant source loads in an urban setting, as well as helping to stabilize eroding banks include the following:

- **Stone Toe Protection:** Non-erodible materials are used to protect the eroding banks of a stream. Meandering bends found in the watershed could potentially be stabilized by placing the hard armor only on the toe of the bank. Stone toe protection is most commonly implemented "using stone quarry stone that is sized to resist movement and is placed on the lower one third of the bank in a windrow fashion" (Kinney 2005).
- **Rock Riffle Grade Control:** Naturally stable stream systems typically have an alternating riffle-pool sequence that helps to dissipate stream energy. Riffle rock grade control places loose rock grade control structures at locations where natural riffles would occur to create and enhance the riffle-pool flow sequence of stable streams. By installing riffle rock in an incised channel, the riffles will raise the water surface elevation resulting in lower effective bank heights, which increases the bank stability by reducing the tractive force on the banks (Kinney 2005).
- **Rock chutes:** Rock chutes are riprap lined water conveyance structures used to move water down a slope in a non-erosive manner. The main purpose of a rock chute is to reduce channel flow velocity by dissipating energy and to provide a stable grade at the outlet to prevent erosion.
- **Silt Fences:** Silt fences are temporary fences used for sediment control. Silt fences are inexpensive and simple to implement, and function by trapping sediment behind the fence, rather than allowing it to continue into waterways.
- **Gabions:** Gabions are mesh cages filled with rocks, broken concrete, and sand and soil, and are sometimes used in the construction of retaining walls. Gabions provide extra support for erosion control structures, helping to minimize sediment transport into waterways.

Street Sweeping – Street sweeping is the practice of passing over an impervious surface, usually a street or a parking lot, with a vacuum or a rotating brush for the purpose of collecting and disposing of accumulated debris, litter, sand, and sediments. Street sweeping is widely practiced by urban and suburban governments for litter and dust control. In addition, many commercial establishments utilize street sweeping for aesthetic reasons.

For street sweeping to have a beneficial effect on water quality in urban areas, a schedule of frequent sweeping must be established. There are several types of street sweepers, some of which are more effective than others at removing certain types of nonpoint source pollution.

Street sweeper (Mill City Times 2016)

Some examples of street sweeping devices include mechanical sweepers, vacuum assisted mechanical sweepers, regenerative cleaners, industrial type vacuum sweepers, hand sweepers, and street flushers, although vacuuming is ideal so that sediment will not simply be redeposited within the same land area. The physical removal of particulates and attached fine pollutant particles from the street surface will lessen the pollutant load transferred to receiving waters.

Studies have shown that there are certain times when street sweeping is very effective in improving water quality. In areas with defined wet and dry seasons, sweeping prior to the wet season is likely to be beneficial, and is highly effective at reducing chloride loads to streams. Other times when sweeping is beneficial are following snow melt and heavy leaf fall (Northern Virginia 1997). The current extent of street sweeping in the watershed, type of equipment used, and program schedules are currently unknown. Each local jurisdiction in the watershed should be encouraged to review their existing program and make adjustments, as needed, to include pollutant removal and water quality improvements program goals.

Conservation Tillage Practices: While most of the land around the impaired stream segments is urban, conservation tillage practices could help reduce sediment loads into the portions of the impaired segments adjacent to agricultural land by reducing erosion of soils. In conservation tillage, at least 30 percent of the soil surface retains cover by residue after planting. Crop residuals or living vegetation cover on the soil surface protects against soil detachment from water and wind erosion.

Conservation tillage practices are grouped into three types: no-till, ridge-till, and mulch-till. No one method is best for all fields; instead, the decision on the type of conservation tilling to be used should be based on factors such as the severity of the erosion problem, the soil type, crop rotation, and available equipment. No-till leaves the soil undisturbed from harvest to planting thus leaving a high percentage of surface covered by crop residues. No-till planting can be done successfully in chemically-killed sod, in crop residues from the previous year, or when double-cropping after a small grain. The planting is done in a narrow (usually 6 inches or less) seedbed

or slot created by coulters, row cleaners, disk openers, in-row chisels, or roto-tillers. A press-wheel follows to provide firm soil-seed contact. Herbicides are the primary method of weed control, although cultivation may be used for emergency weed control.

Ridge-till involves planting into a seedbed prepared on ridges with sweeps, disk openers, coulters, or row cleaners. The ridges are rebuilt during cultivation and, except for nutrient injection, the soil is left undisturbed from harvest to planting. Ridge-till systems therefore leave residue on the surface between ridges so the degree of soil conservation depends on the amount of residue and the row direction. Planting on the contour and increased surface coverage greatly reduce soil loss. Ridge-till works best on nearly level, poorly drained soils. The ridges speed up drainage and soil warm-up. Cultivation controls weeds along with some herbicides.

Mulch-till uses chisel plows, field cultivators, disks, sweeps, or blades to till the soil before planting. The tillage does not invert the soil but leaves it rough and cloddy. Various chisel points or sweeps attached to the shanks affect the amount of residue cover left on the soil surface. The effectiveness of mulch-till systems in reducing erosion depends on surface roughness, amount of residue, and tillage direction. Fall chiseling should be done to a depth of 8-10 inches, and spring chiseling should be no deeper than 6 inches. Disking or other shallow tillage operations can be used in seed bed preparation. A standard, or tandem, disk does not till as deep and leaves more residue on the surface compared to heavy (offset) disks. Herbicides and/or cultivation controls weeds in a mulch-till system.

Conservation tillage practices can remove approximately 75 percent of the sediment and up to 45 percent of the dissolved and total phosphorus from runoff. Additionally, studies have found around 93 percent less erosion occurred from no-till acreage compared to acreage subject to moldboard plowing (USEPA 2003). Tillage practices, particularly adjacent to the HBDA-01 and HBDC-02 impaired segments should be assessed and possibly improved upon to reduce sediment loads.

3.4 BMP Recommendations for Reducing TSS and Sedimentation/Siltation in Sauk Trail Lake

It should be noted that Sauk Trail Lake (RHI) is scheduled to have its dam removed in 2021-2022, by the US Army Corp of Engineers. Since the lake was created by damming Thorn Creek, removing the dam should effectively eliminate Sauk Trail Lake. The dam removal will have a host of positive environmental impacts, including ecosystem restoration and correcting habitat damage. When the dam is removed, the TMDL for Sauk Trail Lake will no longer be relevant.

TSS and NVSS load reductions are needed for Sauk Trail Lake in order to meet the watershed-specific LRS target value. The percent reductions needed for TSS in Sauk Trail Lake are discussed in **Section 2.4.3**. Nonpoint source controls designed to reduce erosion and overland flow are expected to reduce TSS in lakes as well as provide a secondary benefit of reducing other contaminants such as excess nutrients that may be entering waterways via erosive processes. **Figure 2-4** in the AECOM Stage 1 report for the Thorn Creek watershed (AECOM 2011) shows the land around the lake to be primarily urban and forested. The BMPs discussed in **Section 3.3** are also applicable to TSS impairments within the lake.

A **stormwater retention basin, sand filtration basin, and/or bio-retention cell** could be constructed at the upstream end of the lake. **Filter strips; riparian buffers; vegetated swales; permeable pavement; compost blankets, berms, and socks; and stormwater reduction techniques** may also be employed in select areas to help control overland flow and the associated transport of sediment and pollutants.

For the **filter strips**, potential tributary and shoreline buffer areas were calculated using average slopes in the subbasin as described in **Section 3.3**. The average slopes, appropriate filter strip flow lengths, and calculated areas within the buffer distances for Sauk Trail Lake are provided in **Table 3-4**. The table also shows estimated acres of open land surrounding the lake and its tributaries where filter strips could potentially be installed. Landowners or managers should be encouraged to evaluate their land adjacent to the impaired lake to determine the practicality of installing or extending filter strips to achieve effective flow lengths as previously described. **Figure 3-6** depicts the buffered areas and open lands suitable for conversion to filter strips in the lake's subbasin.

Table 3-4: Average Slopes, Filter Strip Flow Length, Total Buffer Area, and Area of Land within Buffers Potentially Suitable for Conversion to Filter Strips, by Lake

Waterbody Name	Segment ID	Average Slope (%)	Filter Strip Flow Length (feet)	Total Area in Buffer (Acres)	Potentially Convertible Land in Buffer (Acres)
Sauk Trail Lake	RHI	11	234	51.6	4.87

For the **riparian buffers**, potential tributary and shoreline buffer areas were estimated as described in **Section 3.3** and are shown in **Table 3-5**. Landowners or managers should be encouraged to assess parcels adjacent to the impaired lake and maintain or improve existing riparian areas or potentially convert semi-developed lands.

Table 3-5: Total Area and Area of Grassland, Forest, and Agricultural Land within 25-Foot Buffer of Impaired Lake and its Major Tributaries

Stream Name	Segment ID	Area in 25 ft Buffer (Acres)	Grassland in 25 ft Buffer (Acres)	Forest in 25 ft Buffer (Acres)	Agricultural Land in 25 ft Buffer (Acres)
Sauk Trail Lake	RHI	4.96	0.01	1.82	0

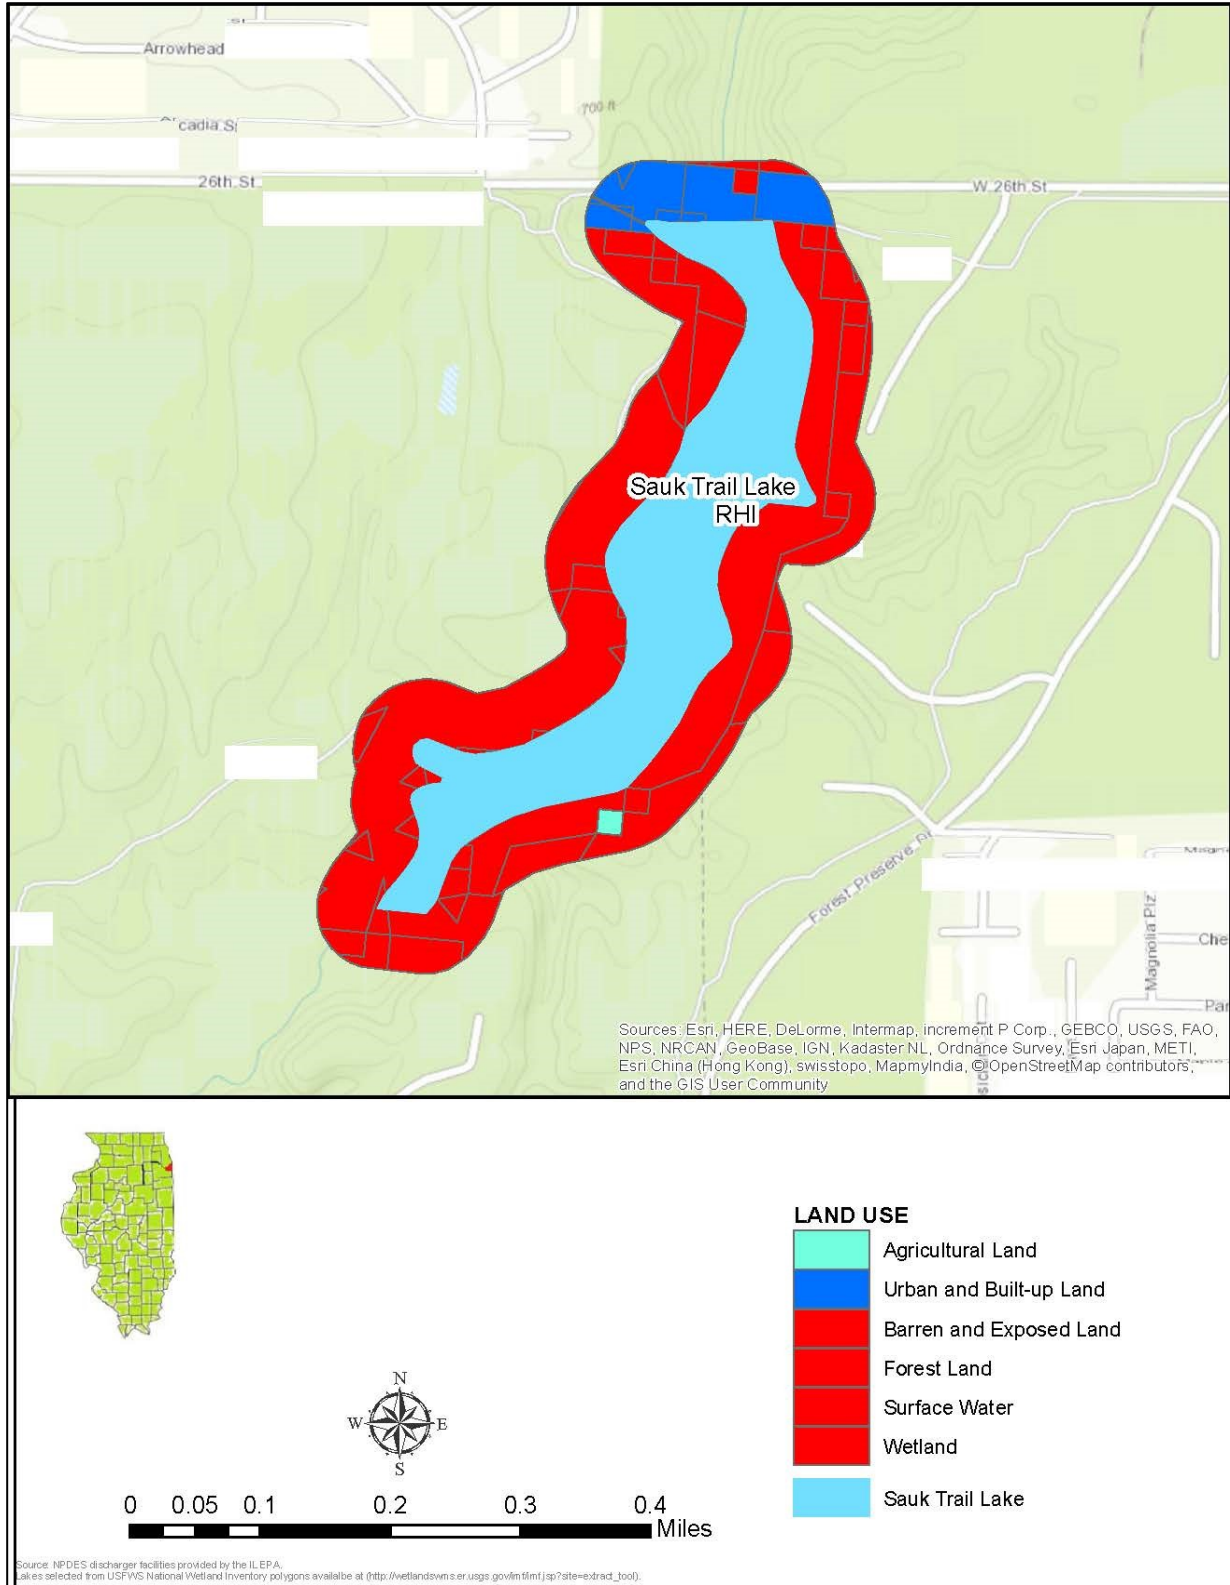

Figure 3-6: Sauk Trail Lake Segment RHI Buffer Land Uses Suitable for Conversion to Filter Strips

Wetlands could potentially be constructed at the lake where higher inflow rates are observed. The use of wetlands as structural controls was discussed in **Section 3.3**. For Sauk Trail Lake, hydric soils with potential for wetland construction are shown in **Figure 3-7**, along with existing wetlands, to indicate potential areas where wetlands may be installed for the lake's subbasin. Areas near the lake not currently classified as wetlands, but which have hydric soils present, are typically strong candidates for potential wetland construction. Existing wetland areas may also be candidates for reconstruction or enhancement to improve their nutrient uptake capacity. These data layers are developed on a large-scale and onsite soil investigation and wetland delineation is typically necessary for verification of the suitability of a given area for wetland construction.

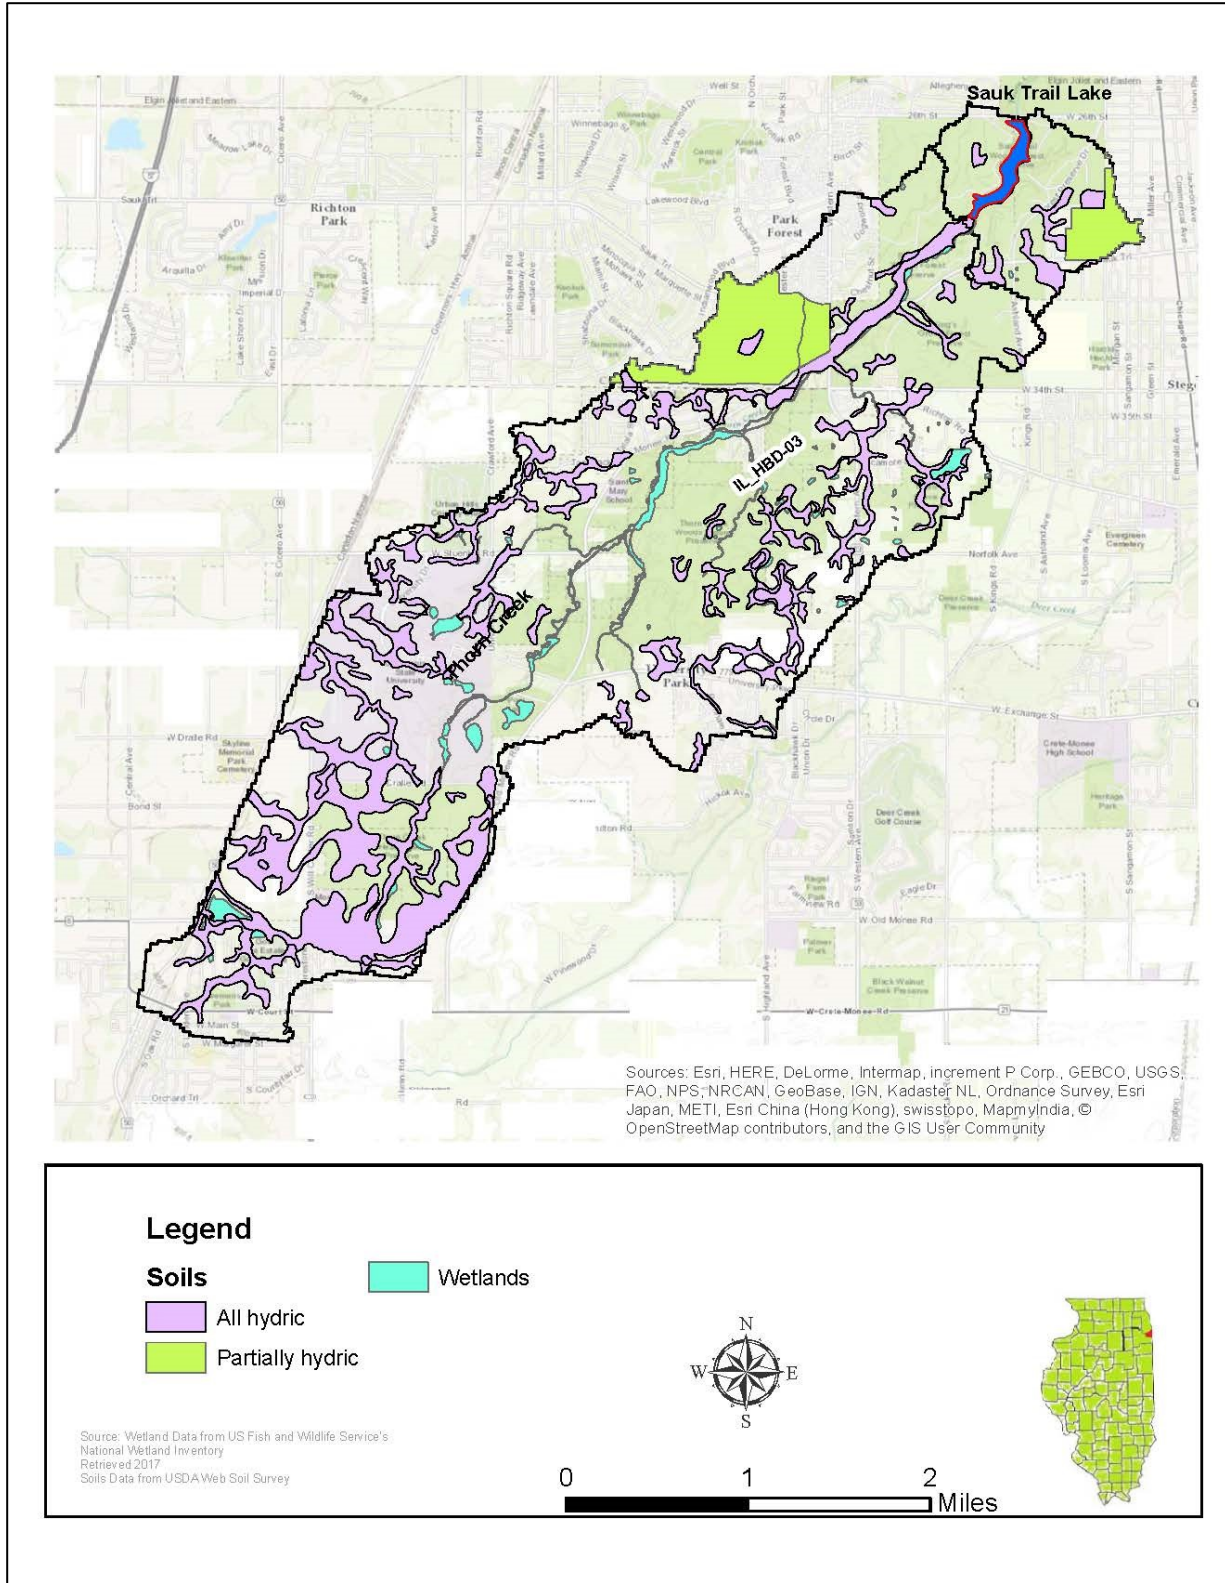

Figure 3-7: Sauk Trail Lake Segment RHI Hydric Soils and Wetlands

Shoreline stabilization/erosion control techniques could be used along the shoreline in select areas of the lake to deflect energy from water movement and minimize erosion. Techniques include engineered structures such as buried revetments and rip rap zones. The selected structures should be placed where higher inflow rates are observed and/or where erosion caused by wave action and other factors is observed.

- Buried revetments: These are passive, sloped, engineering structures designed to deflect energy associated with water movement and reduce erosion. The revetments are populated with native vegetation which can also reduce the transport of sediment associated pollutants via the control of shoreline soil erosion resulting from stormwater runoff.

The extent of bank erosion surrounding the Sauk Trail Lake is unknown. Further investigation is recommended to determine the extent that erosion control measures could help manage TSS loads in the lake.

3.5 BMP Recommendations for Reducing Total Phosphorus and Increasing DO in Sauk Trail Lake

As discussed in Section 3.4, Sauk Trail Lake is scheduled to be removed in 2021-2022. Sauk Trail Lake (RHI) has reported exceedances of the 0.05 mg/L water quality standard for total phosphorus in lakes and is therefore listed for impairment by total phosphorus. Phosphorus is a nutrient critical to healthy ecosystems at low concentrations; however, over enrichment of phosphorus can result in aquatic ecosystem degradation when nitrogen is also available in sufficient quantities. Nutrient enrichment can result in rapid algal growth as available nutrients and carbon dioxide are consumed. This response can alter pH, decrease DO (which is critical to other aquatic biota), alter the diurnal DO pattern, and even create anoxic conditions. In addition, nutrient enrichment can reduce water clarity and light penetration and is aesthetically displeasing. Oxygen levels must be considered when evaluating BMPs for phosphorus because phosphorus is released from sediment at higher rates under anoxic conditions; increased water temperature and photosynthesis decrease DO levels and create anoxic conditions.

Inputs of phosphorus originate from both point and nonpoint sources. Most of the phosphorus discharged by point sources is soluble. Phosphorus from point sources also typically has a continuous impact and is human in origin; for example, effluents from municipal sewage treatment plants and permitted industrial discharges. Phosphorus from nonpoint sources is generally insoluble or particulate. Most of this phosphorus is bound tightly to soil particles and enters streams from erosion. The impact from phosphorus discharged by nonpoint sources is typically intermittent and is most often associated with stormwater runoff. Sedimentation can impact the physical attributes of the stream and act as a transport mechanism for phosphorus.

Internal cycling of phosphorus from lake sediments is also a significant contributor to impairments in Sauk Trail Lake. Low DO near the lake bottom during periods of thermal stratification, if present, is generally addressed by focusing on organic loads that consume oxygen through decomposition as well as nutrient loads that can cause algal growth, which can also deplete DO. Sufficient reductions in nutrient loads are expected to alleviate DO issues.

Phosphorus loads in Sauk Trail Lake originate from internal and external sources. Possible external sources of total phosphorus include municipal point sources, lawn and garden activity, agriculture, runoff, and littoral/shore area modifications. To achieve a reduction of total phosphorus for the lake, managerial and institutional BMPs must address internal loading and loading associated with urban and rural runoff.

3.5.1 Point Sources of Phosphorus

While point source loads of phosphorus can be a significant issue in some watersheds, no point source discharges currently exist within the Sauk Trail Lake watershed. MS4 permitted areas do exist in the lake's subbasin; however, these are discussed along with non-MS4 stormwater and urban runoff in the following section.

3.5.2 Nonpoint Sources of Phosphorus

In addition to MS4 and non-MS4 urban stormwater, runoff from undeveloped and park lands are potential nonpoint sources of phosphorus pollution to the impacted lakes in the watershed. Due to the adsorbing nature of phosphorus, in which phosphorus adheres to sediment before being flushed into waterways, BMPs that could be used for treatment of these sources are similar to those discussed in **Section 3.3**, with the addition of in-lake management measures and phosphorus-based lawn fertilizer restrictions. Applicable BMPs are also discussed in Section 4 of the 2014 watershed-based plan addendum. BMPs evaluated that could be utilized to reduce phosphorus sources, in both urban and agricultural settings, include:

Urban BMPs:

- Grass Filter strips
- Urban Reforestation/Forested Riparian Buffer Restoration
- Wetlands
- Stormwater Retention Basins (dry and wet ponds)
- Vegetated Swales
- Permeable Pavement
- Sand Filters
- Compost Blankets, Filter Berms, and Filter Socks
- Stormwater Reduction Techniques
- Bio-Retention Cells
- Streambank Stabilization and Erosion Control
- Street Sweeping
- Phosphorus-based lawn fertilizer restrictions

Most of these BMPs are described in previous sections; however, additional details more specific to lakes are provided below.

A wetland, stormwater retention basin, sand filtration basin, and/or bio-retention cell could be constructed at the upstream end of Sauk Trail Lake. The use of these structural controls was generally discussed in **Section 3.3** and lake specific areas in **Section 3.4**. **Filter strips; riparian buffers; vegetated swales; and stormwater reduction techniques** may also be employed in select areas to help control overland flow and the associated transport of sediment and pollutants. Potential **filter strip** and **riparian buffer** areas for phosphorus control are the same as those for sediment/TSS control as discussed in **Section 3.4**.

In-Lake Phosphorus Loading: Modeling described in **Section 2** determined that internal loading of phosphorus is likely a significant contributor to overall watershed loads. A reduction of phosphorus from in-lake cycling through in-lake management strategies is necessary for attainment of the TMDL load allocations. Internal phosphorus loading can occur when the water above the sediments become anoxic, causing the release of phosphorus from the sediment in a form which is available for plant uptake. The addition of bioavailable phosphorus in the water column stimulates more plant growth and die-off, which may perpetuate or create anoxic conditions and enhance the subsequent release of phosphorus into the water. Internal phosphorus loading can also occur in shallow lakes through release from sediments by the physical mixing and reintroduction of sediments into the water column as a result of wave action, winds, boating activity, and other means.

For lakes experiencing high rates of phosphorus input from bottom sediments, several management measures are available to control internal loading. Three BMP options for the control of internal loading include the installation of an aerator, the addition of aluminum, and dredging.

- **Hypolimnetic (bottom water) aeration** involves an aerator air-release that can be positioned at a selected depth or at multiple depths to increase oxygen transfer efficiencies in the water column and reduce internal loading by establishing aerobic conditions at the sediment-water interface. Installation of an aeration device will also directly contribute to the alleviation of potential DO issues in lakes (Clean-Flo 2016).
- **Phosphorus inactivation by aluminum addition** (specifically aluminum sulfate or alum) to lakes is the most widely-used technique to control internal phosphorus loading. Alum forms a polymer that binds phosphorus and organic matter. The aluminum hydroxide-phosphate complex (commonly called alum floc) is insoluble and settles to the bottom, carrying suspended and colloidal particles with it. Once on the sediment surface, alum floc inhibits phosphate diffusion from the sediment to the water (Cooke et al. 1993).
- Phosphorus release from the sediment is greatest from recently deposited layers. **Dredging** approximately one meter of recently deposited phosphorus-rich sediment can remove approximately 80 to 90 percent of the internally loaded phosphorus without the addition of potentially toxic compounds to the reservoir. Dredging may also contribute to reductions in internal phosphorus loading by increasing the depth of large portions of the waterbody,

reducing the degree of reintroduction of sediments into the water column through physical mixing. However, dredging is more costly than other management options (NRCS 2005).

Phosphorus-Based Lawn Fertilizer Restrictions: Runoff from urban areas may include phosphorus-based fertilizers applied to residential lawns, golf courses, and other surfaces. If used too close to a receiving waterbody, phosphorus present in stormwater runoff will enter the waterbody. Illinois has a statute in place which governs the use of phosphorus-based fertilizers in urban areas: Lawn Care Products Application and Notice Act (415 ILCS 65), and local enforcement of this ordinance by municipalities can make a significant reduction in phosphorus loading. This act includes the following prohibitions for phosphorus-based fertilizers (see act for limited exceptions):

- They shall not be applied to lawns unless it can be demonstrated by soil test that the lawn is lacking in phosphorus when compared against the standard established by the University of Illinois; see the act for exceptions
- They shall not be applied to impervious surfaces
- They shall not be applied within 3 feet of any waterbody if a spray, drop, or rotary spreader is used. If other equipment is used, the fertilizer may not be applied within 15 feet of a waterbody.
- They shall not be applied when the ground is frozen or saturated
- Appropriate lawn markers for the application event and notifications to potentially affected adjacent properties are required

In addition to enforcement of the above rules, BMPs should include education about the statute, and public outreach to increase awareness and compliance.

3.6 BMP Recommendations for Increasing DO in Streams

Within the Thorn Creek watershed, Thorn Creek segments HBD-02, HBD-03, HBD-04, and HBD-06; North Creek segment HBDA-01; and Deer Creek segment HBDC-02 are listed for impairment by low DO. DO impairments are generally addressed by focusing on organic loads that consume oxygen through decomposition and nutrient loads that can cause algal growth, which can also deplete DO. Implementation actions initiated in Thorn Creek watershed for TSS and nutrient load reduction are directly applicable to DO issues as well. Sufficient reductions in nutrient loads to these stream segments are therefore expected to have positive impacts on instream DO levels. In addition, analyses discussed in Section 2 established a relationship between low flows, SOD, nutrients, oxygen-demanding materials (BOD, ammonia-nitrogen, and organic nitrogen), and DO concentrations in the impaired segments; therefore, management measures for these segments will focus on decreasing loads of oxygen-demanding materials to increase DO concentrations.

DO impairments in the Thorn Creek watershed are mostly attributed to low flow or stagnant conditions. Runoff from nonpoint sources likely contributes loading of oxygen-demanding materials in each segment.

Figure 2-4 in the AECOM Stage 1 report for the Thorn Creek watershed (AECOM 2011) shows the land around the HBD-02, HBD-04, HBD-05, and HBD-06 segments to be primarily urban and forested. The figure also shows the lands around the HBDA-01, HBDC, and HBDC-02 segments to consist of urban, forested, and agricultural areas, with some of the agricultural lands immediately adjacent to portions of the impaired stream segments. Therefore, urban and agricultural BMPs are appropriate for different areas of the impaired stream sub-watersheds.

3.6.1 Point Sources of Nutrients and Oxygen-Demanding Materials

Point sources discharging to impaired streams within the Thorn Creek watershed include municipal sewage treatment facilities and industrial dischargers. **Table 1-6** contains permit information on the treatment facilities, as well as model input parameters used in the QUAL2K modeling discussed in **Section 2** of this report. As discussed in **Section 1.5.2.6**, two large municipal treatment facilities discharge to, or upstream of, segments HBD-02, HBD-04, HBD-06, HBDC, and/or HBDC-02. Only one facility is currently subject to effluent limits for total phosphorus, and the another (Innophos, Inc. IL0035220) is only required to monitor for this parameter. Available discharge data shows that the Innophos facility's non-contact cooling water discharge contains high concentrations of phosphorus that may contribute to excess algae growth under current conditions. Note that this facility was permitted but reporting no-discharge for a number of years prior to beginning regular discharges in 2015 and subsequently current loads are not explicitly captured in the existing QUAL2K modeling period for the impaired segments. Alternative application doses and/or employing alternative anti-fouling agents for use in non-contact cooling water operations are common approaches to reducing the phosphorus loads in this type of discharge.

The two existing POTW facilities also discharge oxygen-demanding materials, as measured by BOD. There are also numerous smaller dischargers that discharge phosphorus to the streams in the watershed. The facilities discharge to tributaries of the impaired segments, or in some cases, directly to the impaired stream segments. Percent reduction needs are discussed in **Section 2.3.5** and shown in **Tables 2-29** through **2-34**. While none of the stream segments are impaired specifically for ammonia, it can act as an oxygen-demanding material and reductions in this nutrient are therefore applicable.

In addition, intermittent discharges such as those from the Park Forest Excess Flow Facility (IL0047562) are a potential source of nutrients and oxygen demanding materials during time periods that do not coincide with the critical condition model considered in the TMDL. Load reductions for intermittent discharges should be considered through the implementation of end of pipe controls and green infrastructure installation in order to address the release of oxygen-demanding materials to the waterways during high flows.

Illinois EPA will evaluate the need for point source controls through the NPDES permitting program as each facility's permit is due for renewal. The NPDES permitted facilities' DMRs should continue to be monitored and any violations of the effluent limits at the permitted facilities may prompt further regulatory action.

MS4 permitted areas do exist in each stream's subbasin, however, these are discussed along with non-MS4 stormwater and urban runoff in the following section.

3.6.2 Stormwater Sources (both point and nonpoint) of Nutrients and Oxygen-Demanding Materials

Potential stormwater-related inputs of nutrients and oxygen-demanding materials to the impacted streams in the watershed include MS4 and non-MS4 urban runoff, and runoff from agricultural, undeveloped, and park lands. In addition, inputs are often caused by nutrient applications in urban settings, such as fertilizer inputs on lawns, golf courses, and other intensively used and maintained landscapes. Nutrients adsorb to soils and enters waterways with runoff and erosion, resulting in excessive growth of algae and other aquatic plants, which impairs aesthetics, water quality, and recreational potential.

BMPs that could be used for treatment of these nonpoint sources are similar to those discussed in **Section 3.3**, with the addition of phosphorus-based lawn fertilizer restrictions, as discussed in **Section 3.5.2**. Applicable BMPs are also discussed in Section 4 of the 2014 watershed-based plan addendum. BMPs evaluated that could be utilized to treat nonpoint phosphorus sources therefore include:

- Grass Filter strips
- Urban Reforestation/Forested Riparian Buffer Restoration
- Wetlands
- Stormwater Retention Basins (dry and wet ponds)
- Vegetated Swales
- Permeable Pavement
- Sand Filters
- Compost Blankets, Filter Berms, and Filter Socks
- Stormwater Reduction Techniques
- Bio-Retention Cells
- Streambank Stabilization and Erosion Control
- Street Sweeping
- Phosphorus-based lawn fertilizer restrictions
- Nutrient management (for agricultural areas)

Most of these BMPs are described in previous sections; however, additional details more specific to streams are provided below.

Filter Strips: As discussed in **Section 3.3**, filter strips can be used as a control to reduce a variety of pollutant loads from runoff, including nutrients and oxygen-demanding materials. The calculations associated with development of filter strip areas for TSS and sediment control

described in **Section 3.3** are directly applicable to nutrient loads as well. In addition, the Illinois Urban Manual describes long-term phosphorus removal efficiencies, or treatment factors, of filter strips of various slopes in urban environments and for different soil types. **Table 3-6** provides a summary of the treatment factors for wooded and non-wooded filter strips in urban areas (AISWCD 2013a). See **Table 3-2** and **Figures 3-1** through **3-3** for areas which can potentially be converted to filter strips.

Table 3-6: Filter Strip Treatment Factors based on Land Slope – Wooded (Non-Wooded)

Hydrologic Soil Group	Slope	25 ft	50 ft	100 ft	150 ft	200 ft
A	0-10%	.75 (.95)	.4 (.6)	.2 (.4)	.1 (.3)	0 (.2)
	11-15%	.8 (1.0)	.5 (.7)	.25 (.45)	.1 (.3)	0 (.2)
	16-20%	.8 (1.0)	.7 (.9)	.5 (.7)	.25 (.45)	.1 (.3)
	21-30%	.8 (1.0)	.75 (.95)	.7 (.9)	.6 (.8)	.3 (.6)
B	0-10%	.75 (.95)	.6 (.8)	.4 (.6)	.2 (.4)	.1 (.2)
	11-15%	.8 (1.0)	.75 (.95)	.5 (.7)	.2 (.4)	.1 (.2)
	16-20%	.8 (1.0)	.8 (1.0)	.65 (.85)	.4 (.6)	.2 (.4)
	21-30%	.8 (1.0)	.8 (1.0)	.7 (.9)	.5 (.7)	.3 (.6)
C	0-10%	.8 (1.0)	.7 (.9)	.55 (.75)	.45 (.65)	.35 (.55)
	11-15%	.8 (1.0)	.75 (.95)	.6 (.8)	.5 (.7)	.4 (.65)
	16-20%	.8 (1.0)	.8 (1.0)	.7 (.9)	.6 (.8)	.5 (.65)
	21-30%	.8 (1.0)	.8 (1.0)	.75 (.95)	.65 (.85)	.5 (.75)
D	0-10%	.9 (1.0)	.8 (.65)	.75 (.8)	.7 (.8)	.6 (.75)
	11-15%	.9 (1.0)	.85 (1.0)	.8 (.9)	.75 (.9)	.65 (.8)
	16-20%	.9 (1.0)	.9 (1.0)	.85 (1.0)	.8 (1.0)	.7 (.85)
	21-30%	.9 (1.0)	.9 (1.0)	.9 (1.0)	.8 (1.0)	.75 (.9)

Forested Riparian Buffers: As discussed in **Section 3.3**, riparian buffers can be used as a control to reduce a variety of pollutant loads from runoff, including nutrients and oxygen-demanding materials. The vegetation also serves to reinforce streambank soils, which helps minimize erosion, and the shade provided will reduce solar radiation loading to the stream and will reduce peak temperatures seasonally, as well as limit algal growth, thereby mitigating low DO levels. The calculations associated with development of riparian buffer areas for TSS and sediment control described in **Section 3.3** are directly applicable to nutrient loads as well. See **Table 3-3** for areas which can potentially be converted to riparian buffers.

The Thorn Creek Headwaters Preserve is one BMP that will create stream improvements for segment HBD-03 and segments downstream. This is a 426-acre property acquired by the Forest Preserve District of Will County in 2007-2008. It is currently mostly farmland, but according to the Forest Preserve District's 2014 Thorn Creek Greenway Preserve Improvement and Management Plan, the future goal for this area is to restore it to native prairie and wetland communities. Two projects have already restored a portion of the preserve, as described below under "Wetlands".

Wetlands: The use of wetlands as a structural control was discussed for TSS and sedimentation/siltation for both streams and lakes. Wetlands are also applicable to nutrient reduction from urban lands because they facilitate plant nutrient uptake, thereby filtering water of pollutants (NRCS 2014). A wetland could be constructed anywhere space allows. Existing wetlands may need to be rehabilitated.

Two recent BMP projects occurred in the watershed of Thorn Creek segment HBD-03, both within the Thorn Creek Headwaters Preserve. First, a wetland mitigation project was implemented in 2014. Ninety-three acres were restored to wetland and prairie to compensate for impacts of the IDOT Stuenkel Road/I-57 Interchange project. The second project was the addition of infiltration and a constructed wetland at Will-Center Road, a cooperative project between the Forest Preserve District of Will County and the Village of University Park.

Stormwater Retention Basins: As discussed in **Section 3.3**, these control basins and ponds (“dry” or “wet”) may be used for flood control and treatment of stormwater. Both systems function to settle suspended sediments and other solids typically present in stormwater runoff. In retaining sediment within the basin, nutrients and trace metals can be removed from overland flow/stormwater runoff before it enters the streams.

Vegetated swales, permeable pavement, sand filters, stormwater reduction techniques, bio-retention cells, streambank stabilization measures, and **street sweeping** will reduce the amount of nutrient laden soils and oxygen-demanding materials entering the streams. A reduction in nutrient loads will decrease the biological productivity and, along with the decreased inputs of oxygen-demanding materials, will lead to a reduction in the levels of SOD present in the stream. Instream management measures for DO focus on reaeration techniques such as rock riffles. **Phosphorus-based lawn fertilizer restrictions** are the same as described in **Section 3.5.2**.

Nutrient Management: As noted above, several areas of agricultural land are present in the watershed, including along the impaired Deer Creek segments. Nutrient management programs for these areas could result in reduced nutrient loads to the impaired stream segments in the watershed. Crop management of nitrogen and phosphorus originating in the agricultural portions of the watershed can be accomplished through Nutrient Management Plans (NMPs) that focus on increasing the efficiency with which applied nutrients are used by crops, thereby reducing the amount available to be transported to both surface water and groundwater.

The overall goal of nutrient reduction from agriculture should be to increase the efficiency of nutrient use by balancing nutrient inputs in feed and fertilizer with outputs in crops and animal produce as well as to manage the concentration of nutrients in the soil. The four “Rs” of nutrient management are applying the right fertilizer source at the right rate at the right time and in the right place. It is not unusual for crops in fields or portions of fields to show nutrient deficiencies during periods of the growing season, even where an adequate NMP is followed. The fact that nutrients are applied does not necessarily mean they are available. Plants obtain most of their nutrients and water from the soil through their root system. Any factor that restricts root growth and activity has the potential to restrict nutrient availability and result in increased nutrient runoff.

Reducing nutrient loss in agricultural runoff may be brought about by source and transport control measures, such as filter strips or grassed waterways. The NMPs account for all inputs and outputs of nutrients to determine reductions. NMPs typically include the following measures:

- A review of aerial photography and soil maps

- Recommendation for regular soil testing – Traditionally, soil testing has been used to decide how much lime and fertilizer to apply to a field. With increased emphasis on precision agriculture, economics, and the environment, soil tests have become a logical tool to determine areas where adequate or excessive fertilization has taken place. Additionally, they can be used to monitor nutrient buildup in soils due to past fertility practices and aid in determining maintenance fertilization requirements. Appropriate soil sampling and analysis techniques are described in the Illinois Agronomy Handbook (<http://extension.cropsciences.illinois.edu/handbook/>).
- A review of current and/or planned crop rotation practices
- Establishment of yield goals and associated nutrient application rates – Matching nutrient applications to crop needs will minimize the potential for excessive buildup of phosphorus soil tests and reallocate phosphorus sources to fields or areas where they can produce agronomic benefits.
- Development of nutrient budgets with planned application rates (which may be variable), application methods, and timing and form of nutrient application
- Identification of sensitive areas and restrictions on application when land is snow covered, frozen or saturated

Phosphorus is a primary nutrient input to the oxygen demand models developed to address DO impairments in many stream segments in the Thorn Creek watershed. Regional differences in phosphorus-supplying power are shown in Figure 8-4 of the Illinois Agronomy Handbook (<http://extension.cropsciences.illinois.edu/handbook/>). The differences were broadly defined primarily based on variability in parent material, degree of weathering, native vegetation, and natural drainages. For example, soils developed under forest cover appear to have more available subsoil phosphorus than those developed under grass. In the Thorn Creek watershed in northeastern Illinois, soils are generally considered to have low phosphorus-supplying power; therefore, buildup and maintenance of phosphorus levels are sometimes needed in this area. Application amounts should be determined by periodic soil testing; however, excessively high-phosphorus soil test levels should not be maintained.

While soil test procedures were designed to predict where phosphorus was needed, not to predict environmental problems, the likelihood of phosphorus loss increases with high-phosphorus test levels. Environmental decisions regarding phosphorus applications should include such factors as distance from a significant lake or stream, infiltration rate, slope, and residue cover. One possible problem with using soil test values to predict environmental problems is in sample depth. Normally samples are collected to a 7-inch depth for predicting nutritional needs. For environmental purposes, it would often be better to collect the samples from a 1- or 2-inch depth, which is the depth that will influence phosphorus runoff. Another potential problem is variability in soil test levels within fields in relation to the dominant runoff and sediment-producing zones. Several fertilizer placement recommendations are described in the Illinois Agronomy Handbook. However, given the propensity of phosphorus to bind tightly to soil particles and subsequently enter streams through erosion, the deep fertilizer placement technique may be most appropriate in phosphorus impaired areas such as the Thorn Creek

watershed. Under the deep placement technique, the fertilizer is placed 4 to 8 inches deep into the soil rather than being spread near the surface.

3.7 BMP Recommendations for Reducing Fecal Coliform in Streams

The TMDL analyses performed for fecal coliform bacteria in Thorn Creek segments HBD-02, HBD-03, HBD-04, HBD-05, and HBD-06; Butterfield Creek segment HBDB-03; and Deer Creek segments HBDC and HBDC-02 show that exceedances have been reported over the full range of flow conditions. Elevated fecal coliform concentrations reported during higher flow conditions are likely a result of stormwater runoff and re-suspension of instream fecal material. Elevated fecal coliform concentrations occurring under low flow conditions are likely a result of point source contributions, illicit sewer connections, and/or groundwater inputs.

3.7.1 NPDES Permitted Point Sources of Fecal Coliform

Section 2.3.1.4 discusses NPDES permitted sources for fecal coliform. These sources consist of two large POTWs (Thorn Creek Sanitary District STP and Aqua Illinois – University Park WWTF), two excess-flow POTWs (Homewood Excess Flow Treatment Plant and Park Forest Excess Flow Facility) and two small mobile home park treatment plants (Ely’s Mobile Home Park STP and Paradise Park MHP STP). The facilities are located both on tributaries of the impaired segments and, in some cases, directly discharge effluent to the impaired stream segments. WLAs for fecal coliform were calculated for each facility as described in **Section 2.3.1.4** and are shown in **Table 2-4**.

A number of municipalities and townships within the Thorn Creek watershed have MS4s. WLAs for the MS4 dischargers were calculated based on municipality boundaries, available information obtained from the MWRD, and the proportion of total MS4 area to total watershed area as discussed in **Section 2.3.1.4**. The total MS4 load allocations for fecal coliform applied to the proportion of each municipality within each impaired reach’s subbasin are shown for each applicable flow category in **Tables 2-5** through **2-12**.

Municipalities covered by MS4s are encouraged to review their stormwater plans to ensure that effective BMPs are being used within their systems. Additionally, municipalities should perform assessment and monitoring to find, fix, and prevent illicit discharges. Illicit discharges may be defined as a storm drain that has measurable flow during dry weather containing pollutants and/or pathogens. A storm drain with measurable flow but containing no pollutants is simply considered a discharge. Illicit discharges are frequently caused when the sewage disposal system interacts with the storm drain system. Each illicit discharge has a unique frequency, composition, and mode of entry in the storm drain system. Illicit discharges of other pollutants are produced from specific source areas and operations known as “generating sites.” Knowledge about these generating sites can be helpful to locate and prevent non-sewage illicit discharges. Depending on the regulatory status of specific “generating sites,” education, enforcement and other pollution prevention techniques can be used to manage this class of illicit discharges.

The highest priority in most illicit discharge monitoring programs is to find any continuous and intermittent sewage discharges to the storm drain system. A variety of monitoring techniques can

be used to find the problem areas and then trace the problems back up the stream or pipe to identify the ultimate generating site or connection. Monitoring can sometimes pick up other types of illicit discharge that occur on a continuous or intermittent basis (e.g., wash water and liquid wastes). Monitoring techniques which can be used to find, fix, and prevent illicit discharges include:

- Outfall reconnaissance inventory, including documenting outfall locations and global positioning system coordinates, as well as investigating them for dry weather flow.
- Indicator monitoring at stormwater outfalls and in-stream. This would include collecting samples for fecal coliform analysis.
- Tracking discharges to their source. If detected, the fecal samples can be sourced to find out if it's animal or human. If it's human the pipes/conveyances can be tracked back to find a cross-connection and eliminate it.

Once sewage discharges or other connections are discovered, they can be fixed, repaired or eliminated through several different mechanisms. Communities should establish targeted education programs along with legal authority to promote timely corrections. A combination of rewards and penalties should be available to deal with the diversity of potential dischargers.

Transitory discharges from generating sites can be minimized through pollution prevention practices and well-executed spill management and response plans. These plans should be frequently practiced by local emergency response agencies and/or trained workers at generating sites.

3.7.2 Nonpoint Sources of Fecal Coliform

Several management options have been identified to help reduce fecal coliform counts in the Thorn Creek watershed. These management options focus on the most likely sources of fecal coliform within the basin, such as wildlife, domestic pets, and overland stormwater runoff. Other nonpoint sources for fecal coliform can include septic systems. While the entirety of the watershed is currently within the service area of a municipal sewer system, functional or abandoned septic systems potentially still exist within the watershed, the existence and prevalence of which is not known. BMPs for fecal coliform were originally discussed in **Section 3.3**.

Sand filtration basins, stormwater retention ponds, and bio-retention cells could be constructed near discharge areas to streams. **Filter strips** and **riparian buffers** may also be employed in select areas to help control overland flow and the associated transport of sediment and pollutants. Potential **filter strip** areas for fecal coliform control are the same as those for sediment/TSS control as discussed in **Section 3.3 (Table 3-2 and Figures 3-1 through 3-3)**. Similarly, potential **riparian buffer** areas for fecal coliform control are the same as those for sediment/TSS control as discussed in **Section 3.3 (Table 3-3)**.

Domestic pet waste: According to the Stage 1 TMDL report (AECOM 2011) approximately 200,000 people resided in the Thorn Creek watershed in 2000. Information on the number of people with pets is not available; however, there are still likely several thousand domestic pets

within the watershed. Education of pet owners on the potential impacts of pet waste to streams and lakes should occur periodically. Public meetings; mass mailings; and radio, newspaper, and TV announcements can all be used to remind and inform owners of their responsibility to pick up after their pets.

Septic System Maintenance: Failing or leaking septic systems can be a significant source of fecal coliform pollution. A program that actively manages functioning systems and addresses non-functioning systems could be implemented to reduce the potential bacteria loads from septic systems in the watershed. The USEPA has developed guidance for managing septic systems, which includes assessing the functionality of systems, public health, and environmental risks (USEPA 2005). It also introduces procedures for selecting and implementing a management plan.

It is unclear to what extent businesses, residences, and other structures in the various townships are served by septic vs. municipal sewer systems; however, as noted above, the entirety of the watershed is currently within the service area of a municipal sewer system. If functional or abandoned septic systems still exist within the watershed, these are expected to be limited in number.

The degree of nutrient removal in any existing systems is limited by soils and system upkeep and maintenance. To reduce the discharge of excessive amounts of contaminants from a faulty septic system, a scheduled maintenance plan that includes regular pumping and maintenance of the septic system should be followed. The majority of failures originate from excessive suspended solids, nutrients, and BOD loading to the septic system. Reduction of solids entering the tank can be achieved by limiting the use of garbage disposals.

Septic system management practices can extend the life, and maintain the efficiency, of a septic system. Water conservation practices, such as limiting daily water use or using low flow toilets and faucets, are the most effective methods to maintain a properly functioning septic system. Additionally, septic systems should not be used for the disposal of solids, such as cigarette butts, cat litter, cotton swabs, coffee grounds, disposable diapers, etc. Physical damage to the drain field can be prevented by:

- Maintaining a vegetative cover over the drain field to prevent erosion
- Avoiding construction over the system
- Protecting the area down slope of the system from excavation
- Landscape the area to divert surface flow away from the drain field (Johnson 1998)

The cost of each management measure is highly variable and site-specific data on septic systems and management practices do not exist for the watershed; therefore, homeowners with septic systems should contact their county health department for septic system management costs.

Current protocols for addressing failing septic systems should adhere to the Illinois Private Sewage Disposal Licensing Act and Code "to prevent the transmission of disease organisms, environmental contamination and nuisances resulting from improper handling, storage, transportation and disposal from private sewage disposal systems". Any new, replaced, or

renovated system must be installed by a licensed contractor or the homeowner and permitted through the county health department. The department must receive both an application for permit and the appropriate fee from the contractor/homeowner. Once reviewed and approved, a permit is issued and an inspection of the system is conducted during and after construction. The county health department also investigates private sewage disposal system complaints.

A long-range solution to failing septic systems is connection to a municipal sanitary sewer system. Connection to a sanitary sewer line would reduce existing pollutant sources by replacing failing septic systems with municipal treatment and will allow communities to develop without further contribution of pollutants to impaired waterbodies. Costs for the installation are generally paid over a period of several years (average of 20 years) and help to avoid forcing homeowners to shoulder the entire initial cost of installing a new septic system. In addition, costs are sometimes shared between the community and the utility responsible for treating the wastewater generated from replacing the septic tanks. The planning process is involved and requires participation from townships, cities, counties, businesses, and citizens.

3.8 BMP Recommendations for Reducing Chloride in Streams

Chloride is a conservative ion, does not degrade, and has the potential to accumulate within waterbodies over time. Chloride is toxic to aquatic organisms at high concentrations and, even at lower concentrations, chloride may impact biological community structure, diversity, and productivity. Chloride salts can also affect soil stability and permeability and increase the potential for erosion. Within the Thorn Creek watershed two segments of Thorn Creek (HBD-04 and HBD-06) were listed for impairment of the aquatic life use due to water quality standard exceedances. Reductions of chloride loads needed to meet the TMDL for the impaired segments are discussed in **Section 2.3.2**.

3.8.1 Point Sources of Chloride

There are twelve NPDES permitted point sources present within the Thorn Creek watershed, and these facilities are located both on tributaries of the impaired segments and, in some cases, they directly discharge effluent to the impaired stream segments. Only two of the listed facilities, Aqua Illinois – University Park WWTF and Park Forest WTP have discharge monitoring requirements for chloride. WLAs were calculated for these facilities based on their permitted effluent limits of 500 mg/L. This effluent limit is the same as the most conservative water quality standard and TMDL endpoint of 500 mg/L.

Chloride WLAs for MS4 discharges were calculated as discussed in **Section 2.3.2.4**. Total MS4 load allocations for chloride for municipalities within each impaired reach's subbasin are shown in **Tables 2-23** and **2-24**.

Continued and/or future monitoring of chloride concentrations in effluent from each of the facilities within the watershed will help provide greater certainty on the relative impact of dischargers to the chloride concentrations in the impaired segments.

3.8.2 Nonpoint Sources of Chloride

Land use around the Thorn Creek watershed is approximately 58% urban overall, with denser urban areas towards the downstream end of the watershed. Nonpoint chloride sources may

therefore originate from road de-icing activities using chloride salts. While all of the BMPs listed for TSS and fecal coliform will also benefit the chloride impairment, particularly vegetated swales since they generally line roadways, the following BMPs are specific to chloride and will provide a basis for management of chloride salt application to roadways. Applicable chloride reduction strategies are also discussed in Section 4 of the 2014 watershed based plan addendum.

Public Education and Staff Training: Educating the public is generally the first step in any water quality improvement campaign. Increased awareness about the application of road salt and the effects of excessive loading to waterbodies can increase community support for chloride use reduction. Information about what homeowners and businesses can do to limit chloride salt application in addition to municipal leadership should be included. The following elements could be included in the public education program:

- Informative fact sheets for public distribution. Environmental group outreach lists can be useful and the information could be in a general, adaptive form.
- Presentation or fact sheets targeted to municipal government officials.
- Public access television.
- Newspaper articles or advertisements.
- Declaration of “Limited Salt Use Areas” to highlight water quality protection and increase awareness.

Staff training is critical to reduce the quantity of road salt used as operators responsible for salt handling and application can have the largest impact on overuse and product loss. Elements of a staff training program could include:

- Initial training for new employees, including on-the-job training from experienced personnel. Alternatively, programs are offered by the American Public Works Association and Northeastern Illinois Public Safety Training Academy.
- Routine annual refresher training for salt handling and application with operators highlighting the impacts of road salt on water quality, infrastructure, and associated costs to the public. Proper storage and handling and application equipment and techniques should be covered as well, including record keeping and a review of the salt quantities required for each situation.
- Required training for private snow removal contractors generally involved in parking lot and private road snow removal. This could be done through a licensing or permitting process.

Storage and Handling: Proper storage and handling of road salt limits loss of salt to the environment and provides cost savings. The Salt Institute has published a Salt Storage Handbook (Salt Institute 2015) with recommended practices and design criteria for storage facilities. Additionally, the Transportation Association of Canada has published detailed BMPs for salt storage (TAC 2013). The Illinois Department of Transportation already has standard designs

which can be adopted by municipalities. Existing facilities should be evaluated for improvement and bulk handling practices reviewed. Areas on which to focus evaluation should include protection from environmental conditions like wind and rain, storage on an impervious pad, and controlled offsite drainage. Training on proper handling and equipment inspection practices should include:

- Salt should be handled as little as possible to avoid particle breakdown and loss of material.
- Spillage should be minimized and cleaned up as soon as practicable.

Application: Proper application of salt for snow and ice control is fundamental to obtaining the desired effect of public road safety while minimizing product loss to the environment. Several guidelines and recommendations have been published including the salt Spreading, Maintenance, Application Rates & Timing (SMART) Learning Guide BMPs by the Transportation Association of Canada (TAC 2005) and the Minnesota Local Road Research Board handbook for snowplow operators (LRRB 2012), which was written in conjunction with the Minnesota Department of Transportation.

Records should be kept of salt use for each route, during each storm, by each vehicle, and by each operator. The records should be examined regularly to confirm that the target salt application rates are being met. Plowing snow just prior to salt application is good practice and if side-cast snow accumulation interferes with continued plowing, it should be removed to an offsite disposal facility. There are two alternative application methods which could increase the effectiveness of traditional rock salt application during and after snow events described below.

- Use of a pre-wetting agent has been shown to reduce wasted salt during application, thereby requiring less material and chemicals (Fay et al. 2013). Pre-wetted salt is also more effective than dry salt, in a wider range of temperatures, in terms of de-icing capabilities, as well as adherence to the road surface. Pre-wetting can be done onboard spreader trucks or by pre-treating salt stockpiles before loading trucks.
- Anti-icing programs should strongly be considered in conjunction with deicing programs. This involves the application of deicing agents on roads prior to ice or snow events. Correct timing for application involves use of accurate weather forecasts or weather information systems. These systems may require purchase or equipment modification and employee training.

Alternative Products: Non-chloride deicing products are available for purchase and agencies have well documented their use. It is recommended that a long-term pilot study be done within the watershed to determine effectiveness for this application. Acetate deicers do not contain chloride, but can be relatively expensive. Organic deicers are also relatively expensive, but can be used in select areas, or in combination with other deicing liquids. More detailed information can be found in the Chloride Usage Education and Reduction Program Study (DRSCW 2007) by the DuPage River Salt Creek Workgroup.

3.9 BMP Recommendations for Reducing Silver and Zinc in Streams

Thorn Creek segment HBD-02 is listed for both zinc and silver impairments. Segment HBD-02 requires a 2.6% reduction in silver inputs at mid-range flows and no reduction at higher or lower flows, indicating uncertainty as to whether point or nonpoint sources are responsible. The exceedances as discussed in **Section 1.5.2.5** potentially suggest that the primary source of silver loads into the impaired segment are likely in response to overland runoff and urban stormwater resulting from precipitation events. Segment HBD-02 requires a 30-34% reduction in zinc inputs at high flows and higher moist flows, and a 6% to 16% reduction at lower moist to low flows. Zinc reduction needs indicate that both point and some nonpoint sources are responsible (**Section 1.5.2.4**).

Silver and zinc are common pollutants from industrial sources. Nonpoint sources of zinc include aging galvanized iron and steel, road salt, and tire wear (Schueler and Shepp 1993). Silver has a variety of uses such as photographic purposes, coins, electrical and electronic uses, solder, solar energy, jewelry, and sterling silver and silver electroplated objects.

Zinc can combine with other elements, such as chlorine, oxygen, and sulfur, to form zinc compounds. Most zinc ore found naturally in the environment is in the form of zinc sulfide. Zinc mobility and bioavailability is mainly governed by pH. As with many trace metals, zinc solubility is higher under more acidic conditions. Alkaline conditions favor adsorption of zinc to oxides and oxyhydroxides of iron, manganese, and aluminum; and to clay minerals and organic matter; and sorption and/or precipitation with carbonate minerals. Organic matter appears to play a more important role on zinc adsorption as compared to the hydroxides. Under low reduction-oxidation conditions, zinc may form insoluble sulfides. Naturally-occurring chelating agents, such as many organic acids, can increase the solubility and mobility of zinc.

Silver is found in both elemental form and in various ores such as argentite (silver sulfide) and horn silver (silver chloride). Commercially, the main sources of silver are copper, copper-nickel, gold, lead, and lead-zinc ores. Silver is also extracted from the anode waste sludges of electrolytic copper-refining. Silver is stable in oxygen and water, but tarnishes when exposed to sulfur compounds in air or water to form a black sulfide layer. Inorganic and organic components of water influence silver speciation in waste water effluent and may affect silver toxicity. Cationic and anionic constituents of aqueous systems control ionic strength which affect metal solubility. Organic materials such as humic and fulvic acids are capable of complexing silver and other metals in solution. It is also entirely possible that silver combines with ions and/or organic material to form suspended solids which are measured as aqueous silver. This suspended silver may be less available for bioaccumulation than soluble forms of silver. Lower bioavailability of silver reduces the toxicity observed for silver solutions.

3.9.1 Point Sources of Silver and Zinc

Dischargers within the Thorn Creek watershed tributary to segment HDB-02 are discussed in **Sections 2.3.3.4** and **2.3.4.4**. One permittee is required to monitor for both silver and zinc, one permittee is required to monitor for zinc, and one permittee is required to monitor for silver; however, none of these permittees have permit limits for these metals. None of the other

permittees have permit limits or monitoring requirements for silver. One permittee, a POTW, has permit limits for zinc. No point sources have been identified in the watershed that discharge high concentrations of silver or zinc. Continued and/or future monitoring of zinc and silver concentrations in effluent from each permitted facility within the watershed will help provide greater certainty on the relative impact of dischargers to the zinc and silver concentrations in the impaired segment.

MS4 load allocations for zinc and silver for municipalities within the impaired reach's subbasin are also discussed in **Sections 2.3.3.4** and **2.3.4.4**. BMPs for the MS4s are discussed along with non-MS4 stormwater and urban runoff in the following section.

3.9.2 Nonpoint Sources of Silver and Zinc

In addition to MS4 and non-MS4 urban stormwater, runoff from undeveloped, park, and agricultural lands are potential nonpoint sources of zinc and silver pollution to the impacted stream segment. The following BMPs are recommended to reduce the loading of silver and zinc to Thorn Creek.

For naturally-occurring nonpoint sources, filter strips, stormwater retention basins, vegetated swales, and streambank stabilization/erosion control practices may provide the secondary benefit of reducing any contaminants that may be attached to the soil, primarily by limiting the amount of zinc- or silver-enriched sediment or water flowing into the stream segment. These control practices were described in **Section 3.3**.

Additional BMPs for zinc and silver include chemical or passive treatment methods. Active chemical treatment typically involves the addition of other chemicals, such as calcium carbonate, sodium hydroxide, sodium bicarbonate, and anhydrous ammonia, to create a reaction, decrease the solubility of dissolved metals, and precipitate metal salts which then settle out of solution. Active chemical treatment is not likely to be a viable option for the HBD-02 stream segment because the chemicals are expensive and the treatment system requires additional costs associated with operation and maintenance, as well as the disposal of metal-laden sludge. Chemical addition and energy consuming treatment processes are virtually eliminated with passive treatment systems, and the operation and maintenance requirements of passive systems are considerably less than active treatment systems. Examples of passive treatment technologies include the following:

Aerobic Wetland: An aerobic wetland consists of a large surface area pond with horizontal surface flow. These wetlands can only effectively treat water that is net alkaline (pH greater than 7). In aerobic wetland systems, metals are precipitated through oxidation reactions to form oxides and hydroxides. A typical aerobic wetland will have a water depth of 6 to 18 inches and can be planted with cattails and other wetland species (Zipper et al. 2011).

Compost or Anaerobic Wetland: Compost, or anaerobic, wetlands, consist of a large pond with a lower layer of organic substrate. A typical compost wetland will have 12 to 24 inches of organic substrate and be planted with cattails or other emergent vegetation (Zipper et al. 2011). Typically, the compost layer consists of spent mushroom compost that contains about 10 percent calcium carbonate. Other compost materials include peat moss, wood chips, sawdust, or hay. The

flow is horizontal within the substrate layer of the basin. Piling the compost a little higher than the free water surface can encourage the flow within the substrate.

Open Limestone Channels: Open limestone channels may be the simplest passive treatment method available. These channels are constructed in two ways. The first method collects contaminated drainage water within a drainage ditch constructed of limestone while the second method consists of placing limestone fragments directly in a contaminated stream. In either case, dissolution of the limestone adds alkalinity to the water and raises the pH causing precipitation of the metals. This treatment requires large quantities of limestone for long-term success (Zipper et al. 2011).

Diversion Wells: Diversion wells are another simple way to increase the alkalinity of contaminated waters. Acidic water is conveyed by a pipe to a downstream "well," which contains crushed limestone aggregate. The hydraulic force of the pipe flow causes the limestone to turbidly mix and abrade into fine particles preventing armoring (Zipper et al. 2011).

Anoxic Limestone Drains: An anoxic limestone drain is a buried bed of limestone constructed to intercept subsurface mine water flow and prevent contact with atmospheric oxygen. Keeping oxygen out of the water prevents oxidation of metals and armoring of the limestone. An anoxic limestone drain can be considered a pre-treatment step to increase alkalinity and raise pH before the water enters a constructed aerobic wetland (Zipper et al. 2011).

Vertical Flow Reactors: Vertical flow reactors were conceived as a way to overcome the alkalinity producing limitations of anoxic limestone drains and the large area requirements of compost wetlands. The vertical flow reactor consists of a treatment cell with an under-drained limestone base topped with a layer of organic substrate and standing water. The water flows vertically through the compost and limestone and is collected and discharged through a system of pipes. The vertical flow reactor increases alkalinity by limestone dissolution and bacterial sulfate reduction (Zipper et al. 2011).

3.10 Cost Estimates of BMPs

Cost estimates and payment rate estimates for a number of suggested BMPs are provided in the following sections. For some BMPs, "average" costs are not available due to design considerations such as size, construction materials, and site-specific conditions. Information for **Sections 3.10.1** through **3.10.3** was obtained from the Illinois EQIP List of Eligible Practices and Payment Schedule documents located at (<https://www.nrcs.usda.gov/wps/portal/nrcs/main/il/programs/financial/eqip/#eqipbene>).

3.10.1 Filter Strips and Riparian Buffers

Several types of filter strip practices are available, including areas for native herbaceous vegetation with or without fertility measures required and areas of introduced species, also with or without fertility measures required. Filter strip implementation that includes seedbed preparation and native seed application ranges from \$520/acre to \$639/acre depending on the type used.

Riparian buffers consisting of trees and shrubs can vary in costs depending on the type of material planted and the density of plantings required. Per unit costs and payments for bare-root trees and shrubs are estimated at \$1.65 per tree and \$1.10 per shrub. Direct seeding of trees and/or shrubs costs approximately \$741/acre. The direct seeding scenario includes a planting rate of approximately 3,000 seeds per acre and both include the foregone income for the land taken out of crop production. Land preparation, including removing undesirable vegetation and improving site conditions, is estimated at \$38-42/acre. For cases where an herbaceous cover is preferable, such as native grass or certain species of forbs and/or shrubs, costs/payments average \$662/acre.

3.10.2 Nutrient Management Plan – NRCS

According to the Stage 1 report (AECOM 2011), only about 19% of the Thorn Creek watershed is comprised of agricultural land; however, areas where agricultural land does exist may benefit from NMPs. Estimated costs and EQIP payments for nutrient management range from \$13/acre (basic) to \$45/acre (enhanced nutrient management with deep placement [at least 4 inches below surface] of manure and/or phosphorus fertilizer). The cost for developing a NMP ranges from \$1,740 to \$2,901/plan depending on the acreage to be managed under the plan and assuming that a comprehensive NMP is not required. NMP preparation includes soil testing, manure analysis, scaled maps, and site-specific recommendations for fertilizer management.

3.10.3 Nutrient Management Plan – IDA and Illinois EPA

The costs associated with development of a NMP co-sponsored by the Illinois Department of Agriculture (IDA) and the Illinois EPA is estimated at \$10/acre paid to the producer and \$3/acre for the third party vendor who develops the plan. There is a 200 acre cap per producer. The total plan development cost is estimated at \$13/acre.

3.10.4 Wetlands

The price to establish a wetland is very site specific and depends on factors such as size and type of vegetation used. Examples of costs associated with constructed wetlands include excavation costs, vegetation removal, and revegetation costs. Costs for wetlands created on a flat mineral uplands where surface runoff may be intercepted and ponded by excavation range from \$3,186 (no embankment) to \$3,679 (with embankment). Some areas may favor a wetlands setting requiring only to be enhanced or restored. In an area of natural depression fed by surface runoff, enhancement/restoration is approximately \$2,557/acre. Enhancing or restoring a wetland on a floodplain site that has existing levees and/or ditches may consist of regrading or shaping the land, potentially including levee removal, for \$1,167/acre. Constructed wetlands to reduce the pollution potential of runoff and wastewater average \$7,724/acre where natural regeneration of wetland plants will be a major contributor to the working vegetation and \$10,286/acre where wetland vegetation in the pool area is planted at a denser grid (3-foot by 3-foot or closer). As needed, embankments, water control and grade stabilization structures, and filter strips should be added.

3.10.5 Streambank Stabilization/Erosion Controls

Streambank stabilization and erosion control measures will vary greatly in cost and EQIP payment and may cover a variety of techniques. Costs may be as low as \$38/cubic yard for full

bank armor on the streambank, including earthwork, rip rap (in which loose stone is used for bank stability), and/or geotextile (which is permeable fabric that helps reinforce streambanks). Alternatively, costs may be as high as \$53/linear foot for bank protection using peaked stone toes (stones placed to secure the lower portion of a streambank), stream barbs (rock sills projecting out from a streambank, meant to redirect flow away from an eroding bank), and/or bendway weirs (low level rock dikes angled upstream, altering the stream's secondary currents and controlling excessive channel deepening) (NRCS 2016).

Alternatively, turf reinforcement mats (TRMs) may be used to reinforce vegetation and protect soil from erosion. TRMs are protective reinforced materials formed into a non-degradable mat, and may be appropriate where vegetation alone will not sustain long term erosion protection, and where other options may be limited due to landscape features such as mowing, which may be prominent in the Thorn Creek watershed (AISWCD 2013b). Implementation of TRMs may cost approximately \$0.60/square foot, or to \$26,136/acre (NRCS 2016), and can be as little as one-third the cost of rip rap (Pack 2008). Prices vary greatly and are dependent upon the steepness of the slope that is being treated, and the vegetation and anchor types being used, which are dependent upon the expected velocities that the TRMs will be expected to withstand (Propex 2007).

Additionally, conservation cover may be implemented and may range in price from \$583.66/acre to \$1,243.89/acre. Conservation cover involves the establishment of permanent vegetation cover, and costs are dependent on the type of vegetation, whether or not organic seed is used, and the ecosystem type into which the vegetation is being introduced (NRCS 2016).

3.10.6 Vegetated Swales

Vegetated swales vary in size and may include checks, depending upon the slope of the area in question. Costs and EQIP payments range from \$2,569/acre for a vegetated swale with a top width less than 35 feet and no checks, to \$4,015/acre for a vegetated swale with a top width greater than 55 feet and with checks (NRCS 2016).

3.10.7 Green Roofs

Green roofs are relatively new technology in the United States and costs are estimated to average between \$15/square foot to \$20/square foot. These cost estimates are for all use types; i.e., high density residential, commercial, and industrial (Urban Design Tools 2016).

3.10.8 Bio-Retention Cells

Bio-retention cells, otherwise known as rain gardens, range in cost depending upon the permeability of the soil and the vegetation types used within the cell. Where highly permeable soils are present, costs range from \$1.50 to \$3.00/square foot. Where soils are less permeable, costs may range from \$4.00 to \$6.00/square foot (Penn State Extension 2016).

3.10.9 Conservation Tillage

Conservation tillage is assumed to include tillage practices that preserve at least 30 percent residual cover of the soil after crops are planted. Costs associated with converting to conservation tillage will depend on the extent and degree of conservation tillage practices implemented. A no-till/strip-till system, organic or non-organic, involves managing the amount, orientation, and

distribution of crop and other plant residue on the soil surface year-round while limiting soil-disturbing activities used to grow and harvest crops. These systems average approximately \$16/acre. Incorporating mulch till in place of conventional till costs \$4.21/acre, and applies to both organic and conventional fields. A full-width ridge-till system costs approximately \$30/acre. Contour farming is a practice in which row orientation is changed from up and down hill orientation to nearly perpendicular to the flow of runoff. Costs for this practice are \$6.06/acre.

3.10.10 Septic System Maintenance

Septic tanks are designed to accumulate sludge in the bottom portion of the tank while allowing water to pass into the drain field. If the tank is not pumped out regularly, the sludge can accumulate and eventually become deep enough to allow for flow into the drain field. Pumping the tank every three to five years prolongs the life of the system by protecting the drain field from solid material that may cause clogs and system back-ups. In addition, septic systems should not be connected to field tile lines.

The cost to pump a typical septic tank ranges from \$250 to \$350 depending on how many gallons are pumped out and the disposal fee for the area. If a system is pumped once every three to five years, this expense averages out to less than \$100 per year.

The cost of developing and maintaining a watershed-wide database of the onsite wastewater treatment systems in the Thorn Creek watershed depends on the number of systems that need to be inspected and the means by which the systems are inventoried. Education of home and business owners that use onsite wastewater treatment systems should occur periodically. Public meetings; mass mailings; and radio, newspaper, and TV announcements can all be used to remind and inform owners of their responsibility to maintain their systems. The costs associated with education and inspection programs will vary depending on the level of effort required to communicate the importance of proper maintenance and the number of systems in the area. It is unknown at this time how many septic systems are present within the watershed. As noted in **Section 3.7.2**, the entirety of the watershed is currently within the service area of a municipal sewer system. If functional or abandoned septic systems still exist within the watershed, these are expected to be limited in number.

3.11 Information and Education

Public education and participation is a key factor for TMDL and watershed plan implementation. Increased public awareness can increase implementation of BMPs. Small incremental improvements and individual adoption of BMPs can be achieved at a much lower cost compared to the large-scale BMPs identified above. Outreach and education efforts should focus on activities that support the watershed plan goals, including:

- Native landscaping
- Biological and water quality monitoring
- Lake and stream management
- Encouraging native landscaping, including buffers along lakeshores and streambanks

- Buffer strips
- Reducing the use of lawn chemicals (pesticides and phosphorus fertilizers)
- Water conservation
- Green infrastructure

An additional public meeting will be held within the watershed to present the final TMDL results and the implementation plan. Additional recommended activities to support public outreach and education include:

- Websites and social media to publicize meetings, upcoming events, and links to resources
- E-mail updates
- Brochures with information on household pollutant reduction, rain gardens, and fertilizer use
- Educational signs to educate viewers on water quality issues, purpose of BMPs, and environmental stewardship
- Public service announcements

3.12 Ongoing Activities

A number of watershed restoration projects are currently underway in the Thorn Creek Watershed. The following lists some of the recent activities as well as ongoing water quality programs which show a commitment to improving water quality conditions within the watershed. Please contact the supporting entities for additional information on projects currently underway in the watershed.

- **Will Center Road Storm Sewer Outfall Improvements- Village of University Park, Crete-Monee School District, the Forest Preserve District of Will County, and CMT Engineers.** An award-winning infiltration and wetland concept was developed into a green sustainable solution that provides an improvement in run-off water quality, a reduction of water quantity, and a wetland amenity, while protecting the headwaters of Thorn Creek.
- **Thorn Creek Headwaters Wetland Mitigation – Forest Preserve District of Will County and the Illinois Department of Transportation (IDOT).** Restoration of 92 acres of the Thorn Creek Headwaters to provide wetland mitigation credits for IDOT and help achieve restoration goals in the Headwaters area. The project includes drain tile disablement, selective tree and shrub removal, planting native seed, plants, and trees, invasive species control, mowing and prescribed fire to restore and enhance a wetland area. This effort will provide water quality benefits to the upper most reaches of Thorn Creek.

- **Thorn Creek Greenway Preserve Improvement and Management Plan – Forest Preserve District of Will County.** A 2014 guiding document for future planning, improvement, management, restoration and operation of District preserves and greenways. The plan is designed to provide and enhance recreational, ecological, and educational opportunities within the Preserve that contribute to the public appreciation of natural history and the environment.

3.13 Project Funding

Cost-share programs and low-interest loans at the local, state and federal level are available to municipalities, landowners, and homeowners in the watershed to help offset costs of implementing many of the BMPs recommended in this plan. Many involve cost sharing, and some may allow the local contribution of materials, land, and in-kind services (such as construction and staff assistance) to cover a portion or the entire local share of the project. Several of these programs are presented below. In addition to these programs, partnerships between local governments can help to leverage funds. A stormwater utility may also be used to generate local funds for stormwater programs and are becoming more common.

3.13.1 Available State-Level Programs for Nonpoint Sources

The following paragraphs describe a few state-level programs designed to encourage landowners to implement resource-conserving practices for water quality and erosion control purposes. Municipalities should aim to incorporate the recommendations of this plan into their annual budgets and comprehensive improvement plans. In general, the majority of funds should come from local efforts; however, the Illinois EPA does offer grants to control nonpoint source pollution in the state. These grants are available to local governments, as well as to other organizations for the purpose of protecting water quality. Projects must address water quality issues relating directly to nonpoint source pollution, and funds can be used to develop, update, and implement watershed management plans. This includes the development of information and education programs, as well as the installation of BMPs.

3.13.1.1 The Conservation Fund

The Conservation Fund, an environmental non-profit, provides low-interest land conservation loans for a variety of conservation projects. Under this fund, land in the Thorn Creek watershed could be converted to green space, providing land for potential wetlands, filter strips, and riparian buffers, and thereby improving water quality (The Conservation Fund 2016).

3.13.1.2 Partners for Conservation

In 1995 the Illinois General Assembly passed the Conservation 2000 bill providing \$100 million in funding over a 6-year period for the promotion of conservation efforts. In 1999, legislation was passed to extend the program through 2009. In 2008, House Bill 1780 was signed into law as Public Act 95-0139, extending the program to 2021 as Partners for Conservation. The Partners for Conservation Program funds programs at Illinois Department of Natural Resources, IDA, and Illinois EPA. Its programs include:

- **Conservation Practices Cost-Share Program:** This program provides monetary incentives for conservation practices implemented on land eroding at a rate of one and

one-half times or more the tolerable soil loss rate. Payments of up to 60% of initial costs are paid through the local conservation districts, which also prioritize and select the projects to be funded in their district. The program provides cost share assistance for BMPs such as cover crops, filter strips, grassed waterways, no-till systems, pasture planting, contour farming, and installation of stormwater ponds. Practices funded through this program must be maintained for at least 10 years. More information can be found at <https://www2.illinois.gov/sites/agr/Resources/Conservation/Pages/default.aspx>.

- **Streambank Stabilization Restoration Program:** The Streambank Stabilization and Restoration Program (SSRP) was established to address problems associated with streambank erosion, such as loss or damage to valuable farmland, wildlife habitat, and roads; stream capacity reduction through sediment deposition; and degraded water quality, fish, and wildlife habitat. The primary goals of the SSRP are to develop and demonstrate vegetative, stone structure, and other low cost bio-engineering techniques for stabilizing streambanks and to encourage the adoption of low-cost streambank stabilization practices by making available financial incentives, technical assistance, and educational information to landowners with critically eroding streambanks. A cost share of 75 percent is available for approved project components such as willow post installation, bendway weirs, rock riffles, stream barbs/rock, vanes, lunger structures, gabion baskets, and stone toe protection techniques. There is no limit on the total program payment for cost-share projects that a landowner can receive in a fiscal year; however, maximum cost per foot of bank treated is used to cap the payment assistance on a per foot basis and maintain the program's objectives of funding low-cost techniques (IDA 2000). All project proposals must be sponsored and submitted by the local Soil and Water Conservation District (SWCD) and recipients of program funding must agree to maintain the implemented practices for at least 10 years. Further information is available at <https://www2.illinois.gov/sites/agr/Resources/Conservation/Pages/default.aspx>.
- **Sustainable Agriculture Grant Program:** This program funds on-farm and university research, education, and outreach efforts for sustainable agricultural practices. Private landowners, organizations, educational, and governmental institutions are all eligible for participation in this program. Maximum per-project, per-year grant amounts are \$10,000 for individuals and \$20,000 for units of government, non-profits, institutions or organizations, and a source of matching funds is required. More information can be found at <https://www2.illinois.gov/sites/agr/Resources/Conservation/Pages/default.aspx>.

3.13.1.3 State Revolving Fund

The State Revolving Fund programs, including the Water Pollution Control Loan Program for wastewater and stormwater projects and the Public Water Supply Loan Program for drinking water projects, are annually the recipients of federal capitalization funding, which is combined with state matching funds and program repayments to form a perpetual source of low interest financing for environmental infrastructure projects. Eligible projects include traditional pipe, storage, and treatment systems, green infrastructure projects, erosion and sediment control projects, and ROW acquisition needed for such projects. The loans are for a maximum of 20 years, and can be used to cover the entire project cost. Recent projects obtained loans for between several hundred thousand dollars and nearly one hundred million dollars. More information

about this fund can be found at <https://www2.illinois.gov/epa/topics/grants-loans/state-revolving-fund/Pages/default.aspx>.

3.13.1.4 Ag Invest Agricultural Loan Program – Annual or Long Term

The Ag Invest Agricultural Loan Program offered through the Illinois State Treasury office provides low-interest loans to assist farmers. Loan funds can be used to implement soil and water conservation practices, for construction related expenses, to purchase farm equipment, or to pay for costs related to traditional crop production and alternative activities. Loan limits are between \$300,000 and \$400,000 per year. More info is available at <https://illinoistreasurer.gov/Invest in Illinois/Ag Invest>.

3.13.1.5 Illinois Buffer Partnership

The Illinois Buffer Partnership is administered by Trees Forever, an Iowa non-profit organization. It offers cost sharing for installation of streamside buffer plantings at selected sites. Ten to twenty participants in Illinois are selected for the program annually. They receive cost-share assistance, onsite assistance from Trees Forever field staff, project signs, and the opportunity to host a field day to highlight their project. Participants are reimbursed up to \$2,000 for 50% of the expenses remaining after other grant programs are applied. Types of conservation projects eligible for the Illinois Buffer Partnership program include: riparian buffers, livestock buffers, streambank stabilization projects, wetland development, pollinator habitat, rain gardens, and agroforestry projects. More information can be found at <http://treesforever.org/Illinois Buffer Partnership>.

3.13.1.6 Illinois Department of Agriculture and Illinois EPA Nutrient Management Plan Project

The IDA and Illinois EPA co-sponsor a cropland Nutrient Management Plan project in watersheds that have developed or are developing TMDLs. This voluntary project supplies incentive payments to producers to have NMPs developed and implemented. Additionally, watersheds that have sediment or phosphorus identified as a cause for impairment (as is the case in this watershed), are eligible for cost-share assistance in implementing traditional erosion control practices through the Nutrient Management Plan project.

3.13.1.7 Vegetative Filter Strip Assessment Law

The Vegetative Filter Strip Assessment Law (35 ILCS 200/10-152), sometimes called the Tax Incentive Filter Strip Program, is a state program that protects water quality by providing a property tax reduction incentive to landowners who install vegetative filter strips between farm fields and an area to be protected, including but not limited to surface water, a stream, or a sinkhole. The filter strips must meet NRCS standards and specifications.

In counties with less than 3,000,000 inhabitants, landowners may receive a reduced property tax assessment of 1/6th of the strip area's productivity value as cropland. In counties with 3,000,000 or more inhabitants, the land shall be valued at the lesser of either 16% of the fair cash value of the farmland estimated at the price it would bring at a fair, voluntary sale for use by the buyer as a farm or 90% of the 1983 average equalized assessed value per acre certified by the Department of Revenue. Landowners can expect to save about \$1 to \$25 per acre in taxes depending on soils and local tax rates. Vegetative filter strip design and certification assistance is available from local SWCD offices.

3.13.2 Available Federal-Level Programs for Nonpoint Sources

There are several voluntary conservation programs established by various federal agencies that encourage landowners to implement resource-conserving practices for water quality and erosion control purposes. Federal-level programs are discussed in the following paragraphs. The USEPA manages the Clean Water Act Section 319 Grants. The Farm Service Agency (FSA) oversees the Conservation Reserve Program (CRP). Voluntary conservation programs established through the 2014 U.S. Farm Bill, and managed by the NRCS, include the Agricultural Conservation Easement Program (ACEP), the Conservation Stewardship Program (CSP), and the Environmental Quality Incentives Program (EQIP).

3.13.2.1 Clean Water Act Section 319 Grants

Section 319 was added to the CWA to establish a national program to address nonpoint sources of water pollution. Through this program, each state is allocated Section 319 funds on an annual basis according to a national allocation formula based on the total annual appropriation for the section 319 grant program. The total award consists of two categories of funding: incremental funds and base funds. A state is eligible to receive USEPA 319(b) grants upon the USEPA's approval of the state's Nonpoint Source Assessment Report and Nonpoint Source Management Program. States may reallocate funds through sub-awards (e.g., contracts, sub-grants) to both public and private entities, including local governments, tribal authorities, cities, counties, regional development centers, local school systems, colleges and universities, local nonprofit organizations, state agencies, federal agencies, watershed groups, for-profit groups, and individuals.

USEPA designates incremental funds, a \$163-million award in 2016, for the restoration of impaired water through the development and implementation of watershed-based plans and TMDLs for impaired waters. Base funds, funds other than incremental funds, are used to provide staffing and support to manage and implement the state Nonpoint Source Management Program. Section 319 funding can be used to implement activities which improve water quality, such as filter strips, streambank stabilization, etc. (USEPA 2003).

Illinois EPA receives federal funds from USEPA through section 319(h) of the CWA to help implement Illinois' Nonpoint Source Pollution Management Program. The purpose of the program is to work cooperatively with local units of government and other organizations toward the mutual goal of protecting the quality of water in Illinois by controlling nonpoint source pollution. The program emphasizes funding for implementing cost-effective corrective and preventative BMPs on a watershed scale; funding is also available for BMPs on a non-watershed scale and the development of information/education nonpoint source pollution control programs.

The maximum federal funding available is 60% of the total cost, with the remaining 40% coming from local match. The program period is two years unless otherwise approved. Approximately \$3,000,000 is available in this program per year, awarded amongst approximately 15 projects.

Projects or activities carried out to comply with the six MS4 minimum control measures are not eligible for section 319 funding. However, there may be some activities that promote opportunities to implement the watershed approach that are eligible for section 319 funding that could indirectly address the six minimum measures as well as nonpoint source projects. For more

information: <https://www2.illinois.gov/epa/topics/water-quality/watershed-management/nonpoint-sources/Pages/default.aspx>.

3.13.2.2 Wetland Program Development Grants

The USEPA provides wetland program development grants to assist state, tribal, and local government agencies, as well as interstate/intertribal entities, in building programs to protect, manage, and restore wetlands (USEPA 2016b).

3.13.2.3 Rivers, Trails, and Conservation Assistance

The National Park Service (NPS) provides financial assistance for the development of natural resource conservation programs, aimed at designing trails and parks, improving access to rivers, protecting special places, and creating recreation opportunities. Applicants may include state and local agencies, tribes, nonprofit organizations, or citizen groups (NPS 2016).

3.13.2.4 Conservation Reserve Program

The CRP may apply to the portion of the Thorn Creek watershed that is agricultural. The CRP is a voluntary program, administered through the FSA, which encourages landowners to agree to remove environmentally sensitive land from agricultural production and plant long-term resource-conserving cover to improve water quality, prevent soil erosion, and reduce loss of wildlife habitat.

Participants can enroll in CRP in two ways and the duration of the contracts under CRP range from 10 to 15 years. The first enrollment method is through a competitive process known as the CRP General Sign-up. These are announced on a periodic basis by the Secretary of Agriculture but do not occur on any fixed schedule. The second enrollment method is through CRP Continuous Sign-up, which is offered on a continuous basis. Continuous sign-up provides management flexibility to farmers and ranchers to implement certain high-priority conservation practices on eligible land. All enrollment offers are processed through the local FSA office.

Certain conditions must be met in order for land to be eligible for CRP enrollment. These conditions include the following:

1. The farmer applying for enrollment must have owned or operated the land for at least 12 months prior to the previous CRP sign-up period (except in cases of a change in ownership due to the previous owner's death, foreclosure, or land purchase by the new owner without the sole intention of placing it in the CRP).
2. Cropland that is planted or considered planted to an agricultural commodity for four of the six most recent crop years (including field margins) and must be physically and legally capable of being planted in a normal manner to an agricultural commodity.
3. Certain marginal pastureland suitable for use as any of the following conservation practices: buffer for wildlife habitat, wetlands buffer or restoration, filter strips, riparian buffer, grass waterway, shelter belt, living snow fence, contour grass strip, salt tolerant vegetation, or shallow water area for wildlife.

In addition to the eligible land requirements, cropland must meet one of the following criteria:

- Have a weighted average erosion index of 8 or higher
- Be expiring CRP acreage
- Be located in a national or state CRP conservation priority area.

The FSA bases rental rates on the relative productivity of soils within each county and the average dryland cash rent or cash-rent equivalent. The maximum rental rate for each offer is calculated in advance of enrollment. Producers may offer land at the maximum rate or at a lower rental rate to increase likelihood of offer acceptance. In addition, the FSA provides cost-share assistance for up to 50 percent of the participant's costs in establishing approved conservation practices (USDA 2016: <https://www.fsa.usda.gov/programs-and-services/conservation-programs/index>). CRP annual rental payments may include an additional amount up to \$2 per acre per year as an incentive to perform certain maintenance obligations (up to \$7 for certain continuous sign-up practice).

Finally, the FSA offers additional financial incentives for certain continuous sign-up practices. Signing Incentive Payment is a one-time incentive payment of \$10/acre for each acre enrolled for each full year of the contract. Eligible practices include field windbreaks; grassed waterways; shelter belts; living snow fences; filter strips; riparian buffers; marginal pastureland wildlife and wetland buffers; bottom timber establishment; field borders; longleaf pine establishment; duck nesting habitat; SAFE buffers, wetlands, trees, longleaf pine, and grass; pollinator habitat; and several wetlands practices. The Performance Incentive Payment is a one-time incentive payment made to participants who enroll land in CRP to be devoted to all continuous sign up practices except establishment of permanent vegetative cover on terraces, wetland restoration (including non-floodplain), bottomland timber establishment, and duck nesting habitat.

The maximum annual non-cost share payment that an eligible “person” can receive under the CRP is \$50,000 per fiscal year. This is a separate payment limitation applying only to CRP non-cost share payment.

3.13.2.5 Conservation Stewardship Program

The CSP may also apply to the portion of the Thorn Creek watershed that is agricultural. The CSP is for agricultural producers who want to maintain or improve existing conservation practices on their land as well as adopt additional conservation activities to address priority resources concerns. Participants earn CSP payments for conservation performance—the higher the performance, the higher the payment.

Through CSP, participants take additional steps to improve resource conditions including soil quality, water quality and quantity, air quality, habitat quality, and energy. CSP provides two types of payments through 5-year contracts: annual payments for installing new conservation activities and maintaining existing practices; and supplemental payments for adopting a resource-conserving crop rotation. Producers may be able to renew a contract if they have successfully fulfilled the initial contract and agree to achieve additional conservation objectives. Payments are made soon as practical after October 1 of each fiscal year for contract activities

installed and maintained in the previous year. In fiscal year 2016, NRCS made \$150 million available for producers through the CSP.

Eligible lands include private and Tribal agricultural lands, cropland, grassland, pastureland, rangeland and non-industrial private forest land. CSP is available to all producers, regardless of operation size or type of crops produced, in all 50 states, the District of Columbia, and the Caribbean and Pacific Island areas. Applicants may include individuals, legal entities, joint operations, or Indian tribes that meet the stewardship threshold for at least two priority resource concerns when they apply. They must also agree to meet or exceed the stewardship threshold for at least one additional priority resource concern by the end of the contract. Producers must have effective control of the land for the term of the proposed contract, which include all eligible land in the agricultural operation. Some additional restrictions and program requirements may apply and interested applicants should contact the local NRCS office for more information. More information about the CSP can be found at

<https://www.nrcs.usda.gov/wps/portal/nrcs/main/national/programs/financial/csp/>.

3.13.2.6 Sustainable Agricultural Grant Program (SARE)

SARE is a U.S. Department of Agriculture program that funds research, education, and outreach efforts for sustainable agricultural practices. Farmer Rancher Grants are for farmers and ranchers who want to explore sustainable solutions to problems through on-farm research, demonstration, and education projects. These grants have funded a variety of topics including pest/disease management, crop and livestock production, education/outreach, networking, quality of life issues, marketing, soil quality, energy, and more. Awards are for a maximum of \$7,500 for an individual project to a maximum of \$22,500 for a group project, and may last up to 24 months. No matching funds are required for this program. About 40 Farmer Rancher grant projects are funded nationwide each year. More information is at <http://www.sare.org/Grants>.

3.13.2.7 Agricultural Conservation Easement Program

ACEP provides financial and technical assistance to help landowners protect, restore, and enhance agricultural and wetlands on their property. Land can be placed into an agricultural land easement or wetland reserve easement. The Agricultural Land Easements component of ACEP has limited applicability to the Thorn Creek watershed but may apply in the approximately 19% that is agricultural. Under the Agricultural Land Easements component, NRCS helps American Indian tribes, state and local governments, and non-governmental organizations protect working agricultural lands and limit non-agricultural uses of the land. Land protected by agricultural land easements provides additional public benefits, including environmental quality, historic preservation, wildlife habitat, and protection of open space. Under the Wetlands Reserve Easements component, NRCS helps to restore, protect, and enhance enrolled wetlands. Wetland Reserve Easements provide habitat for fish and wildlife, including threatened and endangered species, improve water quality by filtering sediments and chemicals, reduce flooding, recharge groundwater, protect biological diversity and provide opportunities for educational, scientific and limited recreational activities.

Agricultural Land Easements: NRCS provides financial assistance to eligible partners purchase Agricultural Land Easements that protect the agricultural use and conservation values of eligible land. In the case of working farms, the program helps farmers and ranchers keep their land in

agriculture. The program also protects grazing uses and related conservation values by conserving grassland, including rangeland, pastureland and shrubland. Land eligible for agricultural easements includes cropland, rangeland, grassland, pastureland and non-industrial private forest land. NRCS will prioritize applications that protect agricultural uses and related conservation values of the land and those that maximize the protection of contiguous acres devoted to agricultural use.

To enroll land through agricultural land easements, NRCS enters into cooperative agreements with eligible partners. Each easement is required to have an agricultural land easement plan that promotes the long-term viability of the land. Under the Agricultural Land component, NRCS may contribute up to 50% of the fair market value of the agricultural land easement. Where NRCS determines that grasslands of special environmental significance will be protected, NRCS may contribute up to 75 percent of the fair market value of the agricultural land easement.

Wetland Reserve Easements: NRCS also provides technical and financial assistance to restore, protect, and enhance wetlands through the purchase of a wetland reserve easement. These agreements include the right for NRCS to develop and implement a wetland reserve restoration easement plan to restore, protect, and enhance the wetland's functions and values. Land eligible for wetland reserve easements includes farmed or converted wetland that can be successfully and cost-effectively restored. NRCS will prioritize applications based the easement's potential for protecting and enhancing habitat for migratory birds and other wildlife. For acreage owned by an Indian tribe, there is an additional enrollment option of a 30-year contract. Through the wetland reserve enrollment options, NRCS may enroll eligible land through one of the following:

- **Permanent Easements** – These are conservation easements in perpetuity. NRCS pays 100 percent of the easement value for the purchase of the easement. Additionally, NRCS pays between 75 to 100 percent of the restoration costs.
- **30-year Easements** – These expire after 30 years. Under 30-year easements, NRCS pays 50 to 75 percent of the easement value for the purchase of the easement. Additionally, NRCS pays between 50 to 75 percent of the restoration costs.
- **Term Easements** – Term easements are easements made for the maximum duration allowed under applicable State laws. NRCS pays 50 to 75 percent of the easement value for the purchase of the term easement. Additionally, NRCS pays between 50 to 75 percent of the restoration costs.
- **30-year Contracts** – 30-year contracts are only available to enroll acreage owned by Indian tribes, and program payment rates are commensurate with 30-year easements.

For wetland reserve easements, NRCS pays all costs associated with recording the easement in the local land records office, including recording fees, charges for abstracts, survey and appraisal fees, and title insurance.

Wetland Reserve Enhancement Partnership – The 2014 Farm Bill replaced the Wetland Reserve Enhancement Program with the Wetland Reserve Enhancement Partnership (WREP) as an enrollment option under ACEP. WREP continues to be a voluntary program through which NRCS

signs agreements with eligible partners to leverage resources to carry out high priority wetland protection, restoration, and enhancement and to improve wildlife habitat.

- Partner benefits through WREP agreements include:
 - Wetland restoration and protection in critical areas
 - Ability to cost-share restoration or enhancement beyond NRCS requirements through leveraging
 - Able to participate in the management or monitoring of selected project locations
 - Ability to use innovative restoration methods and practices

In 2016, NRCS made \$15 million in financial and technical assistance available to help eligible conservation partners leverage local resources to voluntarily protect, restore, and enhance critical wetlands on private and tribal agricultural land nationwide. The funding is provided through the WREP, a special enrollment option under the Agricultural Conservation Easement Program. To enroll, land eligible partners may submit proposals to the local NRCS office. More information is available at

<https://www.nrcs.usda.gov/wps/portal/nrcs/detail/national/programs/easements/acep/?cid=nrcseprd1459249>.

3.13.2.8 Environmental Quality Incentive Program

EQIP is a voluntary program that provides financial and technical assistance to eligible producers to plan and implement conservation practices that improve soil, water, plant, animal, air, and related natural resources on eligible land, including non-industrial private forestland.

Conservation practices eligible for EQIP funding which are recommended BMPs for this watershed include BMPs such as filter strips, riparian buffers, vegetated swales (grass waterways), streambank/shoreline protection, and wetland restoration. More information regarding state and local EQIP implementation can be found at

<https://www.nrcs.usda.gov/wps/portal/nrcs/main/national/programs/financial/eqip/>.

One example in Illinois of the use of EQIP funds in an urbanized area includes a site near East Peoria, where EQIP funds were used prior to site development for the construction of two ponds to include spillway construction, seeding, and mulching (AISWCD 2002).

Under the EQIP program are Conservation Innovation Grants. These grants are anticipated to be available for use by the broader public to leverage federal investment, stimulate innovative approaches, and accelerate technology transfer. Any development proposal that could incorporate conservation BMPs could potentially be eligible under this program. Developers who need to meet local development requirements mandating groundwater protection, buffers and stormwater detention, could utilize this program to help offset implementation costs.

Through EQIP, the NRCS develops contracts with eligible producers to implement conservation practices to address environmental natural resource problems. Persons interested in entering into a cost-share agreement with the NRCS for EQIP assistance may file an application at any time; however, each state may establish deadlines for one or more application periods in which to

consider eligible applications for funding. Applications submitted after the deadlines will be evaluated and considered for funding during later funding opportunities.

Most contracts are for one to three years. EQIP provides payments up to 75 percent of the incurred costs on eligible conservation practices and activities. Payments received by producers through EQIP contracts after February 7, 2014 may not exceed \$450,000 for all EQIP contracts entered into during the period from 2014 to 2018. Payment limitations for organic production may not exceed an aggregate \$20,000 per fiscal year or \$80,000 during any 6-year period for installing conservation practices.

3.13.3 Local Program Contact Information

The Thorn Creek watershed is found in eastern Will County and southern Cook County. This area is served by a single office. Local contact information for the office is listed in **Table 3-7** below.

Table 3-7: Local SWCD and NRCS Contact Information

County	Address	Phone
Will County and South Cook County	1201 S. Gouger Rd New Lenox, IL 60451	(815) 462-3106

3.14 Planning Level Cost Estimates for Implementation Measures

Cost estimates for different implementation measures are presented in **Table 3-8**. The column labeled "Program" or "Sponsor" lists the financial assistance program or sponsor available for various BMPs (as discussed in **Section 3.12**). Illinois EPA 319 Grants are applicable to all of the practices.

Table 3-8: Cost Estimates of Various BMP Measures

BMP	Units	Installation Cost	Program	Sponsor(s)
Filter strip (seeded)	per acre	\$520 - \$639	EQIP	NRCS, IDA
Riparian buffer – bare-root trees/shrubs	each	\$1.10 - \$1.65	EQIP	NRCS, IDA
– forested	per acre	\$741		
– herbaceous cover	per acre	\$642		
– land preparation	per acre	\$38		
Nutrient management	per acre	\$13 - \$45	EQIP	NRCS
Nutrient management plan – federal	per acre	\$1,740 - \$2,902	EQIP	NRCS
– state	per acre	\$13	NMP Project	IDA, Illinois EPA
Bank stabilization	per ft.	\$27 - \$52	SSRP	IDA
– weirs/rock riffles	each	\$2,448 - \$6,305		
– stream barb/bendway weir with longitudinal peaked stone toe	per ft.	\$27.27 - \$52.50		
– bank armor	per c.y.	\$37.55		

BMP	Units	Installation Cost	Program	Sponsor(s)
Vegetated swales	per acre	\$2,569 - \$4,015	EQIP	IDA NRCS
– <35 ft top width	per acre	\$2,569		
– <35 ft top width, with checks	per acre	\$3,284		
– 35-55 ft top width	per acre	\$2,709		
– 35-55 ft top width, with checks	per acre	\$3,516		
– >55 ft top width	per acre	\$3,253		
– >55 ft top width, with checks	per acre	\$4,015		
Wetland – enhancement/restoration	per acre	\$1,167 - \$3,680	ACEP	NRCS
– constructed	per acre	\$7,725 - \$10,286		
Green roofs	per SF	\$15 - \$20		
Bio-retention cell – high permeability soils	per SF	\$1.50 - \$3.00		
– low permeability soils	per SF	\$4.00 - \$6.00		
Conservation tillage			EQIP	NRCS, IDA
– no-till/strip-till	per acre	\$16		
– mulch-till	per acre	\$4.21		
– ridge-till	per acre	\$30		
Contour farming	per acre	\$6.06	EQIP	NRCS
Septic system maintenance	per event	\$250 - \$350	Private system owner	

ac = acre
ft = foot

CY = cubic yard
SF = square foot

3.15 Milestones and Monitoring

3.15.1 Interim Measurable Milestones and Schedule

Successful plan implementation relies on establishing and tracking milestones to measure progress. **Table 3-9** below identifies these milestones and a schedule for meeting each milestone. Stakeholders should evaluate milestone progress on an annual basis and implement adaptive management to modify management measures, milestones, and schedule as necessary.

Implementation of the management actions outlined in this section should occur in phases, often over the course of several years, with effectiveness assessments made as improvements are completed. The process of obtaining funding, and developing and implementing projects designed to improve water quality, can take months or years to complete and once in place, improvements in water quality as a result of BMPs may not be detectable for several years. Continued monitoring and reevaluation of the implementation measures during this time will allow for more expedient adjustment to BMP implementation measures that may result in earlier attainment of water quality targets.

Table 3-9: Implementation Milestones

Milestones	Description	Estimated Schedule
Funding	Develop grant applications	Short term: 2-5 years
Implement Short-term Projects	Identify and implement short-term pilot projects that can be completed (i.e. willing landowners and available funding)	Mid-term: 2-5 years
Monitoring	Implement monitoring plan	Continuous: 1-20 years
Annual Stakeholder meetings	Stakeholders will convene at once a year to gauge progress and discuss evolving needs and planned activities	Annually
Implement Larger Projects	Identify and implement larger projects. These projects are more likely to have multiple funding sources and stakeholders.	Mid- Term: 5-10 years
Education and outreach	Prepare and implement and education and outreach plan. Conduct at least two public meetings annually.	Continuous: 1-20 years

3.15.2 Monitoring Plan

The purpose of the monitoring plan for the Thorn Creek watershed is to assess the overall implementation of management actions outlined in this section. This can be accomplished by conducting the monitoring programs designed to:

- Track implementation of BMPs in the watershed
- Estimate effectiveness of BMPs
- Further monitor of point source discharges in the watershed
- Continued monitoring of impaired lakes, stream segments, and tributaries
- Monitor storm-based high flow events
- Low flow monitoring of nutrients, chloride, zinc, silver, DO, TSS, and fecal coliform in impaired streams and Sauk Trail Lake
- Dry weather monitoring of stormwater outfalls

Tracking the implementation of management measures can be used to:

- Determine the extent to which management measures and practices have been implemented compared to action needed to meet the TMDL endpoints
- Establish a baseline from which decisions can be made regarding the need for additional incentives for implementation efforts
- Measure the extent of voluntary implementation efforts
- Support work-load and costing analysis for assistance or regulatory programs

- Determine the extent to which management measures are properly maintained and operated

Estimating the effectiveness of the BMPs implemented in the watershed could be completed by monitoring before and after the BMP is incorporated into the watershed. Additional monitoring could be conducted on specific structural systems such as a sediment control basin. Inflow and outflow measurements could be conducted to determine site-specific removal efficiency.

Illinois EPA conducts Intensive Basin Surveys every 5 years. Additionally, select ambient sites are monitored nine times a year. Continuation of this state monitoring program will assess lake and stream water quality as improvements in the watershed are completed. This data will also be used to assess whether water quality standards in the impaired segments are being attained.

3.15.3 Success Criteria

Measuring the plan's success depends largely on tracking the milestones outlined above. Implementing BMPs should equate to improved water quality and attainment of designated uses and water quality standards. Monitoring pollutant-load reductions will be the primary success criteria. Key components include:

- Securing funding for priority projects within 5 years
- Meeting milestones identified
- Meeting 25-50% of target reductions within 10 years
- Meeting 100% of target reductions within 20 years
- Utilizing adaptive management to ensure best practices
- Delisting of impaired waterbodies

Section 4

Public Participation

4.1 Thorn Creek Watershed Public Participation Summary

Public knowledge, acceptance, and follow-through are necessary to implement a plan to meet recommended TMDLs and LRSs. It is important to involve the public as early in the process as possible to achieve maximum cooperation and counter concerns as to the purpose of the process and the regulatory authority to implement any recommendations.

Illinois EPA, along with ENSR/AECOM, held a Stage 1 public meeting for the Thorn Creek Watershed at the Park Forest Village Hall facility in Park Forest, Illinois on June 23, 2009. Comments received through the public meeting process are included in Appendix C of the Stage 1 Report.

An additional public meeting was held by Illinois EPA and CDM Smith to present the Stage 3 TMDL results and implementation plan on October 11, 2018 at the Park Forest Village Hall facility in Park Forest, Illinois. A responsiveness summary addressing comments received through the Stage 3 public meeting and public notice process is included in **Appendix G** of this report.

Thorn Creek Watershed TMDL Stage 1 Report

AECOM, Inc
Updated March 2011
Document No.: 10042-003-700

Contents

Executive Summary 1

1.0 Introduction..... 1-1

 1.1 Definition of a Total Maximum Daily Load (TMDL) 1-2

 1.2 Targeted Waterbodies for TMDL Development 1-3

2.0 Watershed Characterization 2-1

 2.1 Watershed Location..... 2-1

 2.2 Topography..... 2-4

 2.3 Land Use..... 2-6

 2.4 Soils..... 2-9

 2.5 Population 2-13

 2.6 Precipitation 2-15

 2.7 Hydrology 2-16

3.0 Public Participation and Involvement 3-1

4.0 Water Quality Standards and TMDL Targets..... 4-1

 4.1 Illinois Pollution Control Program 4-1

 4.2 Designated Uses 4-1

 4.3 Applicable Illinois Water Quality Standards 4-1

 4.4 TMDL Targets 4-2

5.0 Water Quality Assessment 5-1

 5.1 Water Quality Data 5-1

 5.1.1 Dissolved Oxygen..... 5-1

 5.1.2 Fecal Coliform..... 5-1

 5.1.3 Total Phosphorus..... 5-1

 5.1.4 pH..... 5-4

 5.1.5 Copper 5-4

 5.1.6 Chloride..... 5-5

 5.1.7 Silver 5-6

 5.1.8 Zinc..... 5-6

 5.2 Point Sources..... 5-7

 5.3 Non-Point Sources 5-10

6.0 TMDL Approach and Data Needs 6-1

 6.1 Recommended Modeling Approach for Fecal Coliform 6-1

 6.2 Recommended Modeling Approach for Dissolved Oxygen 6-2

 6.3 Recommended Modeling Approach for Total Phosphorus 6-2

 6.4 Recommended Modeling Approach for pH 6-4

 6.5 Recommended Modeling Approach for Metals 6-4

 6.6 Data Needs 6-5

List of Tables

Table 1-1: Illinois' 2008 303(d) List for Thorn Creek Watershed	1-4
Table 1-2: Waterbodies targeted for TMDL development in the Thorn Creek Watershed.....	1-5

List of Appendices

- Appendix A Water Quality Data
- Appendix B NPDES Permit Limits
- Appendix C Stage 1 Responsiveness Summary

Executive Summary

As required by Section 303(d) of the Clean Water Act (CWA), the Illinois EPA (IEPA) is required to identify and list all state waters that fail to meet water quality standards. This list is referred to as the 303(d) list and is revisited every two years to either remove those waters that have attained their designated uses, or to include additional waters not previously deemed impaired. Waterbodies included on the 303(d) list are often targeted for Total Maximum Daily Load (TMDL) development.

A TMDL is an estimation of the maximum amount of a pollutant that a waterbody can receive and still meet water quality standards. It assesses contributing point and nonpoint sources to identify pollution reductions necessary for designated use attainment. A TMDL identifies the source of impairment and provides reduction estimates to meet water quality standards. Pollutant reductions are then allocated to contributing sources, thus triggering the need for pollution control and increased management responsibilities amongst sources in the watershed.

For Thorn Creek 10 impaired waterbodies (out of 12) were identified for TMDL development. The Thorn Creek watershed is located approximately 30 miles south of Chicago and incorporates numerous tributaries of Thorn Creek, including Butterfield Creek, Deer Creek and North Creek. The only waterbody classification applicable to the Thorn Creek watershed is the General Use classification which includes designated uses such as aquatic life, aesthetic quality, and primary contact recreation uses. The identified impairments include dissolved oxygen (DO), fecal coliform, chloride, copper, fluoride, pH, phosphorus (total), silver, and zinc. The water quality criteria identified for these impairments provide an explicit assessment as to whether or not these waterbodies are in compliance. The water bodies were considered impaired if the water quality exceeded the Illinois standards.

Available data used for assessing these waterbodies originated from numerous water quality stations within the Thorn Creek watershed. Data were obtained from both legacy and modernized USEPA Storage and Retrieval (STORET) databases, Thorn Creek Sanitary District data, Metropolitan Water Reclamation District of Greater Chicago (MWRDGC) data, and IEPA database data. Data relevant to impairments were compiled for each impaired waterbody and summary statistics were calculated to further characterize each pollutant.

Various models were recommended for TMDL development, the level of which was primarily based on the complexity of the system and the availability of data. Simple spreadsheet models were recommended for DO TMDLs and the ENSR Lake Response Model (ENSR LRM) was recommended to analyze total phosphorus impairment. Load duration curves were recommended for fecal coliform and metals analyses and could also be used to estimate BOD loading for the DO TMDL. If the system requires a more complex DO model for creek simulation, then QUAL2K could be used. QUAL2K was recommended for the pH TMDL, but is capable of simulating instream DO concentrations.

1.0 Introduction

This Stage 1 Total Maximum Daily Load (TMDL) report is presented as partial fulfillment by the Illinois Environmental Protection Agency (IEPA) and the United States Environmental Protection Agency (U.S.EPA) in the development of TMDLs, as part of that state's Clean Water Act (CWA) Section 303(d) compliance. The purpose of the project is to develop TMDLs for ten impaired waterbodies in the Thorn Creek watershed in northeastern Illinois.

Section 303(d) of the CWA and U.S. EPA's Water Quality Planning Regulations (40 CFR Part 130) require states to develop TMDLs for impaired waterbodies that are not supporting designated uses or meeting water quality standards. A TMDL is a calculation of the maximum amount of pollutants that a waterbody can receive and still meet the water quality standards necessary to protect the designated beneficial use (or uses) for that waterbody. The TMDL process establishes the allowable loadings of pollutants for a waterbody based on the relationship between pollutant sources and water quality conditions, so that states and local communities can establish water quality based controls to reduce pollutants from both point and nonpoint sources and restore and maintain the quality of their water resources.

Water is an essential resource for the inhabitants of the Earth and protecting this resource is the goal for many across the globe. United States policies and regulations, such as the CWA, were created and are implemented to help maintain the quality of our water resources in the United States. The U.S. EPA, via the CWA, charged each state with developing water quality standards (WQS). These WQS are laws or regulations that states authorize to protect and/or enhance water quality, to ensure that a waterbody's designated use (or uses) is (are) not compromised by poor water quality and to protect public health and welfare. In general, WQS consist of three elements:

- The designated beneficial use (e.g., recreation, protection of aquatic life, aesthetic quality, and public and food processing water supply) of a waterbody or segment of a waterbody,
- The water quality criteria necessary to support the designated beneficial use of a waterbody or segment of a waterbody, and
- An anti-degradation policy, so that water quality improvements are conserved, maintained and protected.

The Illinois Pollution Control Board (IPCB) established its WQS in Title 35: Environmental Protection, Subtitle C: Water Pollution, Chapter 1: Pollution Control Board, Part 302: Water Quality Standards. Every two years IEPA submits the Illinois Integrated Water Quality Report and Section 303(d) List. This report documents surface and groundwater conditions throughout the state. The 303(d) List portion of this report identifies impaired water bodies, grouped by watershed, and identifies suspected sources of impairment. These waters are prioritized for TMDL development into high, medium, and low categories based on designated use and pollution severity and are then targeted for TMDL development. Non-pollutant causes of impairment, such as habitat degradation and dissolved oxygen not addressed under the TMDL, but are addressed by programs such as the 319 program and other nonpoint source grant programs.

A TMDL is a calculation of the maximum load a waterbody can receive without exceeding water quality standards or result in non attainment of a designated use. A watershed's TMDL report consists of data analysis to quantitatively assess water quality, documentation of waterbodies or segments of waterbodies that are impaired, and identification of potential contributing sources to impairment. Based on these data, the amount and type of load reduction that is needed to bring water quality into compliance is calculated. The TMDL report provides the scientific basis for states and local communities to establish water quality-based controls to reduce pollutant loads from both point (i.e., wasteload allocations) and non-point sources (i.e., load allocations).

IEPA uses a three-stage approach to develop TMDLs for a watershed:

- **Stage 1** – Watershed characterization, historical dataset evaluation, data analysis, methodology selection, data gap identification;
- **Stage 2** – Data collection to fill in data gaps, if necessary; and
- **Stage 3** – Model calibration, TMDL scenarios, and implementation plans.

The purpose of Stage 1 is to characterize the watershed background; verify impairments in the listed waterbody by comparing observed data with water quality standards or appropriate targets; evaluate spatial and temporal water quality variation; provide a preliminary assessment of sources contributing to impairments; and describe potential TMDL development approaches. If available water quality data collected for the watershed are deemed sufficient by IEPA, Stage 2 may be omitted and Stage 3 will be completed. If sufficient water quality data or supporting information are lacking for an impaired waterbody, then Stage 2 is required and field sampling will be conducted in order to obtain necessary data to complete Stage 3.

This report documents Stage 1 in the IEPA approach for TMDL development. The report is organized into six main sections. Section 1.0 discusses the definition of TMDLs and targeted impaired waterbodies in the Thorn Creek watershed, for which TMDLs will be developed. Section 2.0 describes the characteristics of the watershed, and Section 3.0 briefly discusses the process of public participation and involvement. Section 4.0 describes the applicable water quality standards and water quality assessment. Section 5.0 presents the assessment and analysis of available water quality data. Section 6.0 discusses the methodology selection for the TMDL development, the data gaps, and provides recommendations for additional data collection, if necessary.

1.1 Definition of a Total Maximum Daily Load (TMDL)

According to the 40 CFR Part 130.2, the TMDL (the maximum load a waterbody can be receive without exceeding water quality standards or result in non attainment of a designated use) for a waterbody is equal to the sum of the individual loads from point sources (i.e., wasteload allocations or WLAs), and load allocations (LAs) from nonpoint sources (including natural background conditions). Section 303(d) of the CWA also states that the TMDL must be established at a level necessary to implement the applicable water quality standards with seasonal variations and a margin of safety (MOS) which takes into account any lack of knowledge concerning the relationship between effluent limitations and water quality. In equation form, a TMDL may be expressed as follows:

$$\text{TMDL} = \text{WLA} + \text{LA} + \text{MOS}$$

Where:

- WLA = Waste Load Allocation (i.e., loadings from point sources);
- LA = Load Allocation (i.e., loadings from nonpoint sources including natural background); and
- MOS = Margin of Safety.

TMDLs can be expressed in terms of either mass per time, toxicity or other appropriate measures [40 CFR, Part 130.2 (i)]. US EPA recommends that all TMDLS and associated LA and WLAs be expressed in terms of daily increments but may include alternative non-daily expression of pollutant loads to facilitate implementation of the applicable water quality standard. TMDLs also shall take into account the seasonal variability of pollutant loading and hydrology to ensure water quality standards are met in all seasons and during all hydrologic conditions. Though not required by CWA, IEPA requires that an implementation plan be developed for each watershed, which may be used as a guideline for local stakeholders to restore water quality. This implementation plan will include recommendations for implementing best management practices (BMPs),

cost estimates, institutional needs to implement BMPs and controls throughout the watershed, and time frame for completion of implementation activities.

The MOS accounts for the lack of knowledge or uncertainty concerning the true relationship between loading and attainment of water quality standards. This uncertainty is often a product of data gaps, either temporally or spatially, in the measurement of water quality. The MOS should be proportional to the anticipated level of uncertainty; the higher the uncertainty, the greater the MOS. The MOS is generally based on a qualitative assessment of the relative amount of uncertainty as a matter of best professional judgment (BPJ). The MOS can be either explicit or implicit. If an explicit MOS is used, a portion of the total allowable loading is allocated to the MOS. If the MOS is implicit, a specific value is not assigned to the MOS, but is already factored in during the TMDL development process. Use of an implicit MOS is appropriate when assumptions used to develop the TMDL are believed to be so conservative that they sufficiently account for the MOS.

1.2 Targeted Waterbodies for TMDL Development

In May 2008, IEPA prepared a draft Illinois Integrated Water Quality Report and Section 303(d) List-2008 (commonly referred to as the 303(d) List) to fulfill the requirement of Section 305(b), 303(d) and 314 of the CWA. Under US EPA's review and approval, the report presents a detailed water quality assessment process and results for streams and lakes in the State of Illinois. The water quality assessments are based on biological, physicochemical, physical habitat, and toxicity data. Each waterbody has one or more of designated uses which may include aquatic life, aesthetic quality, indigenous aquatic life (for specific Chicago-area waterbodies), primary contact (swimming), secondary contact (recreation), public and food processing water supply, and fish consumption. The degree of support (attainment) of a designated use in a waterbody (or segment) is assessed as Fully Supporting (good), Not Supporting (fair), or Not Supporting (poor). Waters in which at least one applicable use is not fully supported is designated as "impaired." Potential causes and sources of impairment are also identified for these waters. The 303(d) List is prioritized on a watershed basis based on the requirements of 40 CFR Part 130.7(b)(4). Watershed boundaries are based on United States Geological Survey (USGS) ten-digit hydrologic units, to provide the state with the ability to address watershed issues at a manageable level and document improvements to a watershed's health. TMDL development is also conducted on a watershed basis so that the impaired waters upstream of an individual segment may be addressed at the same time.

Table 1-1 presents the 2008 303(d) List for the Thorn Creek watershed. The table includes impaired designated uses and potential causes. The segments in bold font are scheduled for TMDL development and are the focus of this report. TMDLs will not be developed for the lakes with a surface area less than 20 acres since the Illinois phosphorus standard applies to only those lakes where surface area is 20 or more acres. Further, TMDLs will not be developed for segments impaired by water quality variables that do not have numerical WQS.

Nine river segments and one lake are identified as impaired and selected for TMDL development in the Thorn Creek watershed. The designated uses for these waterbodies are primarily aquatic life with some aesthetic quality and primary contact recreation uses. The identified causes for impairment that have numerical WQS include dissolved oxygen (DO), fecal coliform, chloride, copper, fluoride, pH, total phosphorus, silver, and zinc. The WQS provide numerical criteria to measure compliance for each of these water quality variables. However, DO is considered a non-pollutant by IEPA. The IEPA will ascertain potential causes for low dissolved oxygen using the TMDL process and will develop a TMDL only if the cause is attributable to a pollutant that has a numerical WQS. For example, if a 50-acre lake suffers from low DO due to excessive algal densities which is related to elevated phosphorus concentrations, the IEPA will develop a phosphorus TMDL for this waterbody. TMDLs will not be developed for waterbodies listed as impaired based on non-numerical WQS, such as aesthetic quality impairment with an unknown cause or aquatic life impairment due to insecticides. Waterbodies targeted for TMDL development are listed in Table 1-2.

Table 1-1: Illinois' 2008 303(d) List for Thorn Creek Watershed

Water ID	Waterbody Name	Miles/Acres	Priority	Designated Use	Potential Cause(s)
IL_HBD-02	Thorn Creek	3.68	Medium	Aquatic Life	Aldrin, Chlordane, DDT, Dieldrin, Dissolved oxygen (1), Endrin, Hexachlorobenzene, Total phosphorus, Polychlorinated biphenyls, Silver (1) , Total suspended solids, Zinc (1)
				Primary Contact Recreation	Fecal coliform (1)
IL_HBD-03	Thorn Creek	4.68	Medium	Primary Contact Recreation	Dissolved oxygen (1), Fecal coliform (1)
IL_HBD-04	Thorn Creek	4.13	Medium	Primary Contact Recreation	Fecal coliform (1)
				Aquatic Life	Aldrin, Chlordane, Chloride (1), Copper (1) , DDT, Dieldrin, Endrin, Fluoride (2) , Hexachlorobenzene, pH (1) , Total phosphorus, Polychlorinated biphenyls, Silver (1) , Total suspended solids, Zinc*
IL_HBD-05	Thorn Creek	2.64	Medium	Primary Contact Recreation	Fecal coliform (1)
				Aquatic Life	Total phosphorus
IL_HBD-06	Thorn Creek	1.98	Medium	Primary Contact Recreation	Fecal coliform (1)
				Aquatic Life	Aldrin, Dieldrin, Hexachlorobenzene, pH (1) , Total phosphorus, Silver*
IL_HBDA-01	North Creek	11.66	Medium	Aquatic Life	Aldrin, Hexachlorobenzene, Sedimentation/Siltation
IL_HBDB-03	Butterfield Creek	14.65	Medium	Aquatic Life	DDT, Total phosphorus
				Primary Contact Recreation	Fecal Coliform (1)
IL_HBDC	Deer Creek	6.62	Medium	Primary Contact Recreation	Fecal coliform (1)
				Aquatic Life	Total phosphorus
IL_HBDC-02	Deer Creek	9.17	Medium	Aquatic Life	Total phosphorus, Sedimentation/Siltation
				Primary Contact Recreation	Fecal coliform (1)
IL_RHI	Sauk Trail	28.80	Medium	Aesthetic Quality	Total phosphorus (1) , Total suspended solids
				Aquatic Life	Total phosphorus (1) , Polychlorinated biphenyls, Sedimentation/Siltation, Total suspended solids (TSS)
IL_RHL	Waumpum	35.0	Medium	Aesthetic Quality	Cause unknown

Water ID	Waterbody Name	Miles/ Acres	Priority	Designated Use	Potential Cause(s)
IL_RHR	George (Cook)	8.0	Medium	Aesthetic Quality	Total phosphorus

(1) These parameters have numeric standards and will have TMDL allocations.

(2) These parameters will be recommended for 303(d) delisting as a result of the 2010 Integrated Report assessment.

*The source causing impairment is believed to originate solely from point sources. The point source will be required to meet the water quality standard at the point of discharge. The IEPA, based on the information available, believes that the compliance with the WQS will be achieved after all point source dischargers have installed the appropriate controls. A TMDL will not be prepared for this pollutant at this time, but will assess the waterbody again after the appropriate point source controls have been operational.

Table 1-2: Waterbodies targeted for TMDL development in the Thorn Creek Watershed

Segment ID	Waterbody Name	Waterbody Size (Miles/ Acres)	Designated Use	Impairment
IL_HBD-02	Thorn Creek	3.68	Aquatic Life	Dissolved oxygen, fecal coliform, silver, zinc
IL_HBD-03	Thorn Creek	4.68	Primary Contact Recreation	Dissolved oxygen, Fecal Coliform
IL_HBD-04	Thorn Creek	4.13	Primary Contact Recreation	Dissolved oxygen, fecal coliform, silver, pH, copper, chloride
IL_HBD-05	Thorn Creek	2.64	Primary Contact Recreation	Fecal coliform, dissolved oxygen
IL_HBD-06	Thorn Creek	1.98	Primary Contact Recreation	Dissolved oxygen, fecal coliform, pH
IL_HBDA-01	North Creek	11.66	Aquatic Life	Dissolved oxygen
IL_HBDB-03	Butterfield Creek	14.65	Aquatic Life	Dissolved oxygen, Fecal Coliform
IL_HBDC	Deer Creek	6.62	Primary Contact Recreation	Fecal coliform
IL_HBDC-02	Deer Creek	9.17	Aquatic Life	Dissolved oxygen, Fecal Coliform
IL_RHI	Sauk Trail	28.80	Aesthetic Quality	Dissolved oxygen, phosphorus

2.0 Watershed Characterization

This section describes the general characteristics of the Thorn Creek watershed including location (Section 2.1), topography (Section 2.2), land use (Section 2.3), soil information (Section 2.4), population (Section 2.5), climate and precipitation (Section 2.6) and hydrology (Section 2.7).

2.1 Watershed Location

A watershed is a geographic area that shares a hydrologic connection - all the water within that area drains to a common waterway. Water movement can be influenced by topography, soil composition and water recharge (i.e. precipitation, snow melt, groundwater)¹. Watersheds are important because pollution at the water's source may impact water quality in all downgradient areas including its convergence with a common waterway. Understanding the watershed is an essential step in the TMDL process – an essential tool in maintaining water quality standards within Illinois.

Located about 30 miles south of Chicago, the Thorn Creek watershed (a sub-watershed of the larger Chicago watershed) consists of Thorn Creek, its tributaries (Butterfield Creek, Deer Creek, Third Creek, and North Creek), engineered ditch systems (such as Lansing Ditch and State Street Ditch), and numerous small lakes and wetlands (Figure 2-1). In total, over 65 miles of streams wind throughout 104 square miles of northeastern Illinois and three square miles of northwestern Indiana. Most streams of the Thorn Creek watershed flow from southwest to northeast from their origins in Eastern Will County to their confluence with Thorn Creek and continue to the Little Calumet River in southern Cook County. North Creek, however, flows west from its headwaters in northeastern Indiana, receiving additional drainage from the Lansing Ditch system and then meanders northwest to its junction with Thorn Creek (Figure 2-1). The TMDL watershed segments are identified on Figure 2-2.

The Thorn Creek watershed is further sub-divided into four sub-watersheds, each related to one of its major creeks. The Thorn Creek watershed drains more than 66,000 acres from the area encompassing the western most point near Frankfort, IL to its easternmost point in northwestern Indiana and from the southern most point outside of Monee, IL to the northern most point near South Holland, IL. General characteristics of the major streams within the Thorn Creek watershed are given in Table 2.1.

Table 2-1: Thorn Creek Watershed Stream Characteristics

Stream	Length (<i>approx. miles</i>)	Area drained (<i>square miles</i>)	Area drained (<i>acres</i>)
Butterfield Creek	16	26	16,356
Thorn Creek	17	32	20,441
Deer Creek	16	26	16,801
North Creek	12	20*	12,924

* An additional 3 square miles of the North Creek watershed exists in Northeastern Indiana. This TMDL report, however, covers only the Illinois portion of Thorn Creek watershed.

Figure 2-1: Thorn Creek Watershed Overview

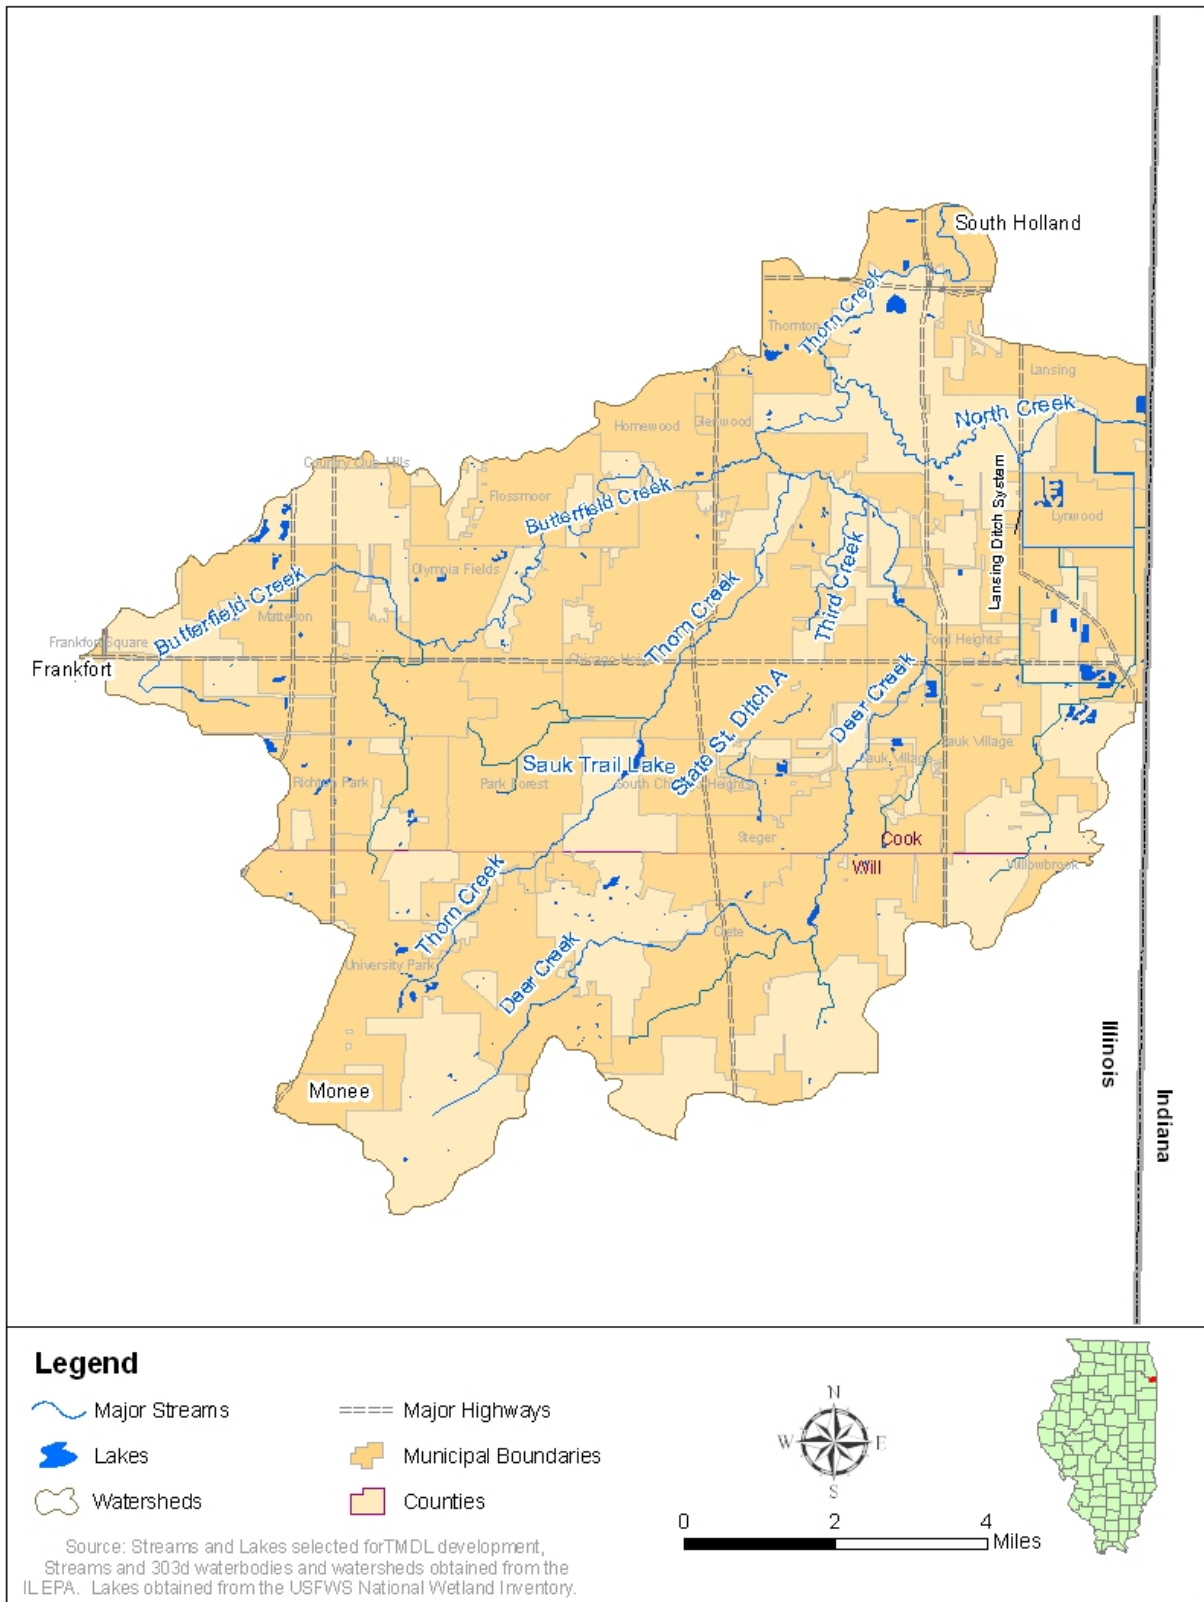

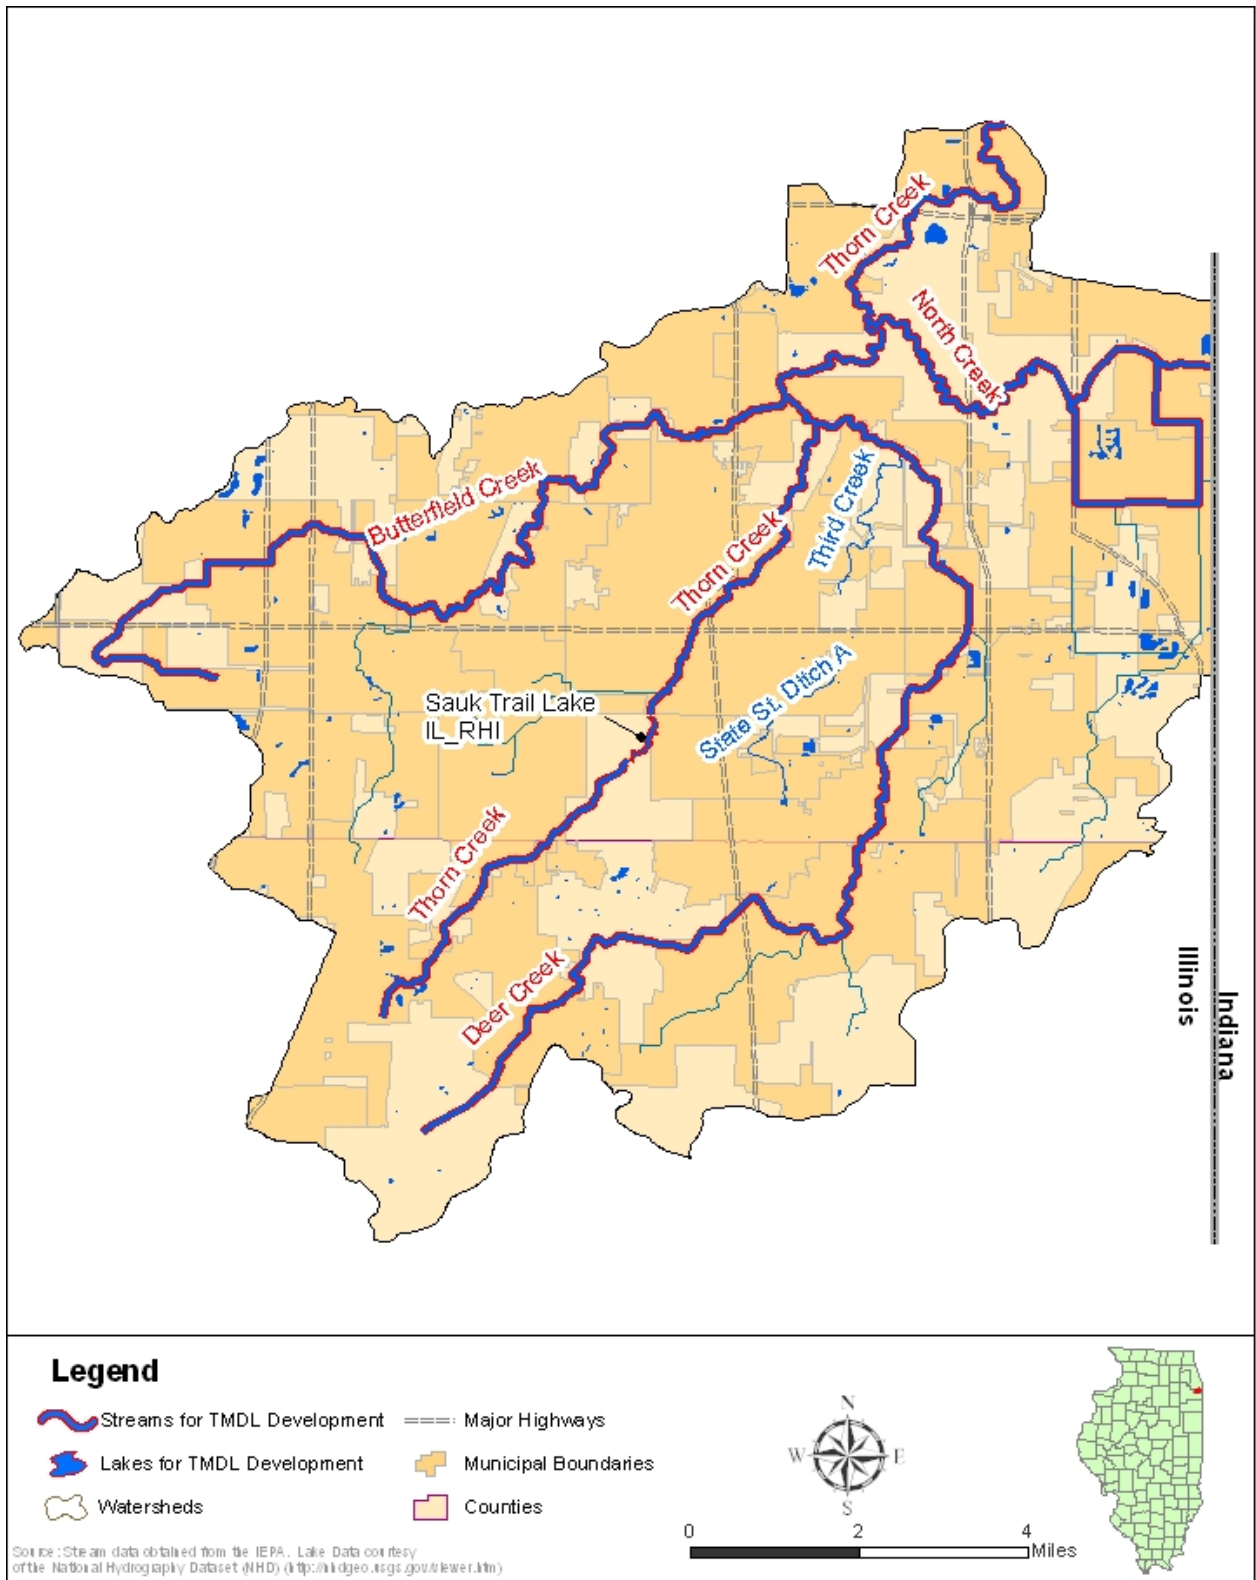

Figure 2-2: Thorn Creek Watershed TMDL Waterbodies

2.2 Topography

Topography influences soil types, precipitation, and subsequently watershed hydrology and pollutant loading. For the Thorn Creek watershed, a USGS 30-meter resolution Digital Elevation Model (DEM) was obtained from the Illinois Natural Resources Geospatial Data Clearinghouse to characterize the topography. Figure 2-3 displays elevations in color ramp throughout the watershed.

The land surface of the Thorn Creek watershed owes its relief to two major influences: large ancient waterbodies and glaciation events. The result is two distinct physiographic regions that are still apparent despite modern developments.

The northeastern third of the watershed is relatively flat, interrupted only by two beach ridges (the Calumet and the Glenwood). This area marks the southernmost edges of the Chicago Lake Plain and moraines associated with the Wisconsinian Glaciation. Hundreds of millions of years ago, before the glaciers, this area was part of an inundated basin covered by warm, shallow seas: the remains of which are still found as fossil evidence in the Thornton quarries and throughout the basin. Later, waters left behind by the last retreat of the glaciers formed prehistoric Lake Chicago; the remnant of these waters became Lake Michigan.

Located on the Chicago Lake Plain and north of the creek's connection to the Lansing Ditch system, North Creek meanders slowly along 12 miles from the Indiana border. North Creek's average channel slope is just over 1 foot per mile, with only 14 feet difference between its 610 feet elevation at the Indiana border and the 596 feet of elevation at its junction with the main stem of Thorn Creek. The North Creek watershed consists of the main stem of North Creek (flowing from east to west) and the Lansing Ditch system (flowing from south to north; linking twice to North Creek). The Lansing Ditch system was originally engineered in 1862 to improve farming opportunities and alleviate drainage problems by channeling off excess waters to North Creek. North Creek has cut a relatively wide, shallow, meandering channel from east to west across the northeastern portion of the Thorn Creek watershed.

The southwestern two-thirds of the watershed is a broad upland that is the result of glaciations. Composed of the Tinley and the Westmont Moraines, as well as, other associated ground moraines of the Valparaiso system, the topography is rolling and deeply cut by Butterfield, Thorn and Deer Creeks. The southern-most boundary of this portion marks the historic mid-continental divide between the Great Lakes/North Atlantic and Mississippi/Gulf of Mexico watersheds². Rain falling in the Thorn Creek watershed has the Great Lakes (and North Atlantic) as its ultimate destination: rain falling south and south west of this boundary, is directed, ultimately, to the Mississippi River and on to the Gulf of Mexico.

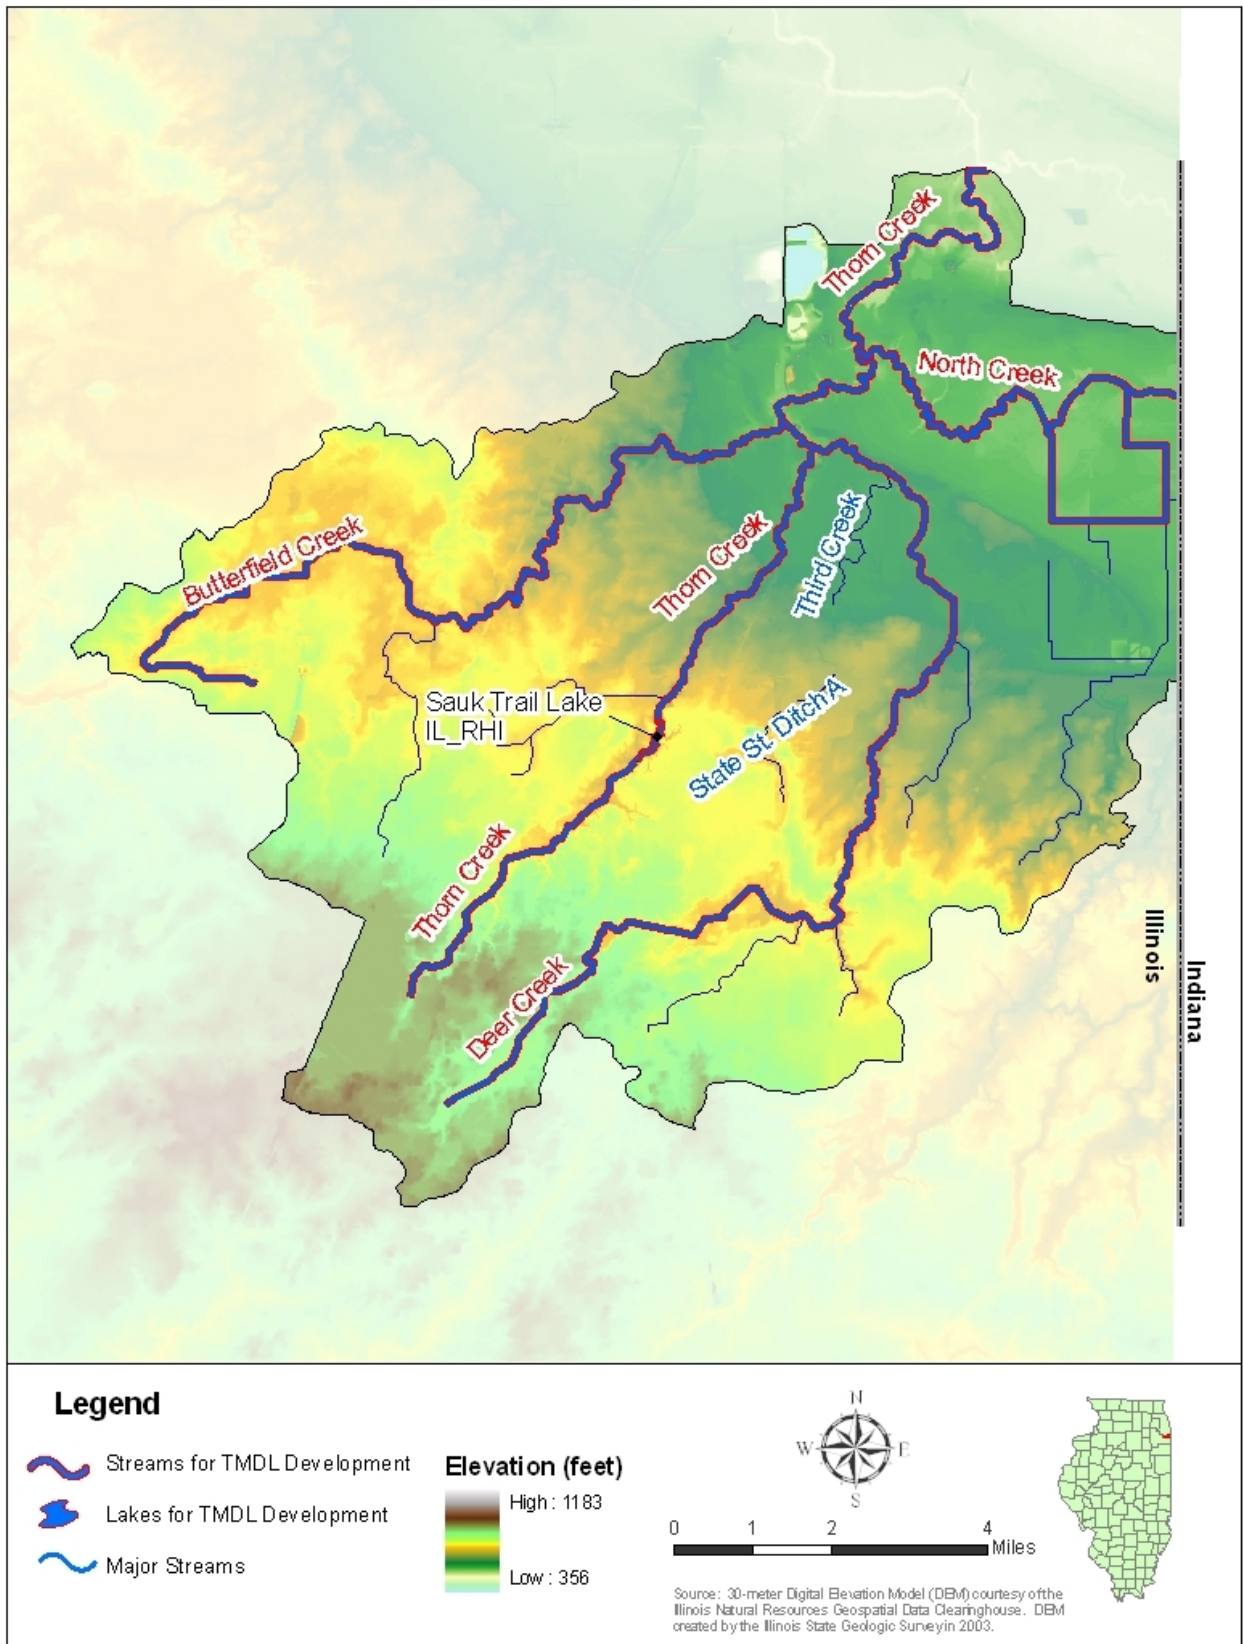

Butterfield Creek, in the southwestern most portion of the watershed, is approximately 16 miles long and drains about 26 square miles (16,356 acres). It has a moderate channel slope of 5-8 feet per mile, and like Thorn and Deer creeks, it has a small but well-defined valley³. From the headwaters just outside of Frankfort, IL to its junction with the main stem of Thorn Creek, Butterfield Creek is entirely within Illinois. Butterfield Creek flows from southwest to northeast; from the upland out onto the Chicago Lake Plain.

The main stem of Thorn Creek also flows from the southwestern upland out onto the Chicago Lake Plain as it joins the Little Calumet in the northeast carrying the aggregate drainage of the entire watershed. Thorn Creek's headwaters begin in the Westmont moraine just south of University Park, continue along the western margin of glacial period Lake Steger, cross the Tinley moraine at a low point in Chicago Heights, and enter the Little Calumet River after traversing about six miles of the Lake Chicago Plain.

² A Watershed Plan for Thorn Creek in Southern Cook County & Eastern Will County, Illinois. 2000.

³ Illinois Department of Natural Resources. 2000. Thorn Creek: An Inventory of the Regions Resources.

Figure 2-3: Thorn Creek Watershed Digital Elevation Model (DEM)

The elevation change from the headwaters, at 790 feet, to its confluence with the Little Calumet, at 585 feet, gives an average channel slope gradient of 10 feet per mile. However, unlike North Creek's gradual channel slope over its length, Thorn Creek has a substantial difference in the channel gradient occurring in the upland moraine portion of the watershed as compared to the gradient occurring on the Chicago Lake Plain. On the plain the gradient is less than 3 feet per mile, while the gradient on the upland portions is over 17 feet per mile⁴. This pattern of stream channel gradient change, from upland gradient to lake plain gradient, is repeated in Butterfield and Deer Creeks as well.

Deer Creek's general orientation is from the southwest to northeast. This 16 mile creek drains about 26 square miles (16, 801 acres). Its headwaters lie in an area between the Wheaton and Westmont moraines in the southeastern most portion of the watershed. The difference in headwater elevation (748 ft.) and the elevation at its junction with the main stem of Thorn Creek (608 ft.) give an average stream channel slope gradient of about nine feet per mile.

2.3 Land Use

Land use is as dynamic as the water moving throughout a watershed. It is constantly changing and has a large impact on the water quality within a watershed. Land use data for the watershed were extracted from the Illinois Gap Analysis Project (IL-GAP) Land Cover data layer. IL-GAP was started at the Illinois Natural History Survey (INHS) in 1996, and the land cover layer was the first component of the project. The IL-GAP Land Cover data layer is a product of the Illinois Interagency Landscape Classification Project (IILCP), an initiative to produce statewide land cover information on a recurring basis cooperatively managed by the United States Department of Agriculture National Agricultural Statistics Service (NASS), the Illinois Department of Agriculture (IDA), and the Illinois Department of Natural Resources (IDNR). The land cover data were generated using 30-meter grid resolution satellite imagery taken during 1999 and 2000. The IL-GAP Land Cover data layer contains 23 land cover categories, including detailed classification in the vegetated areas of Illinois.

Thorn Creek watershed's original landscape of prairie, forest-savanna mosaics, and wetlands gave way to agricultural use beginning as early as 1820³. By the 1860's farmers were actively engineering a ditch system in the Lansing/Lynwood area of the Chicago Lake Plain in order to improve drainage and increase the agricultural usability of the land. Changes in land use from natural areas to agricultural to urban have been steadily progressing.

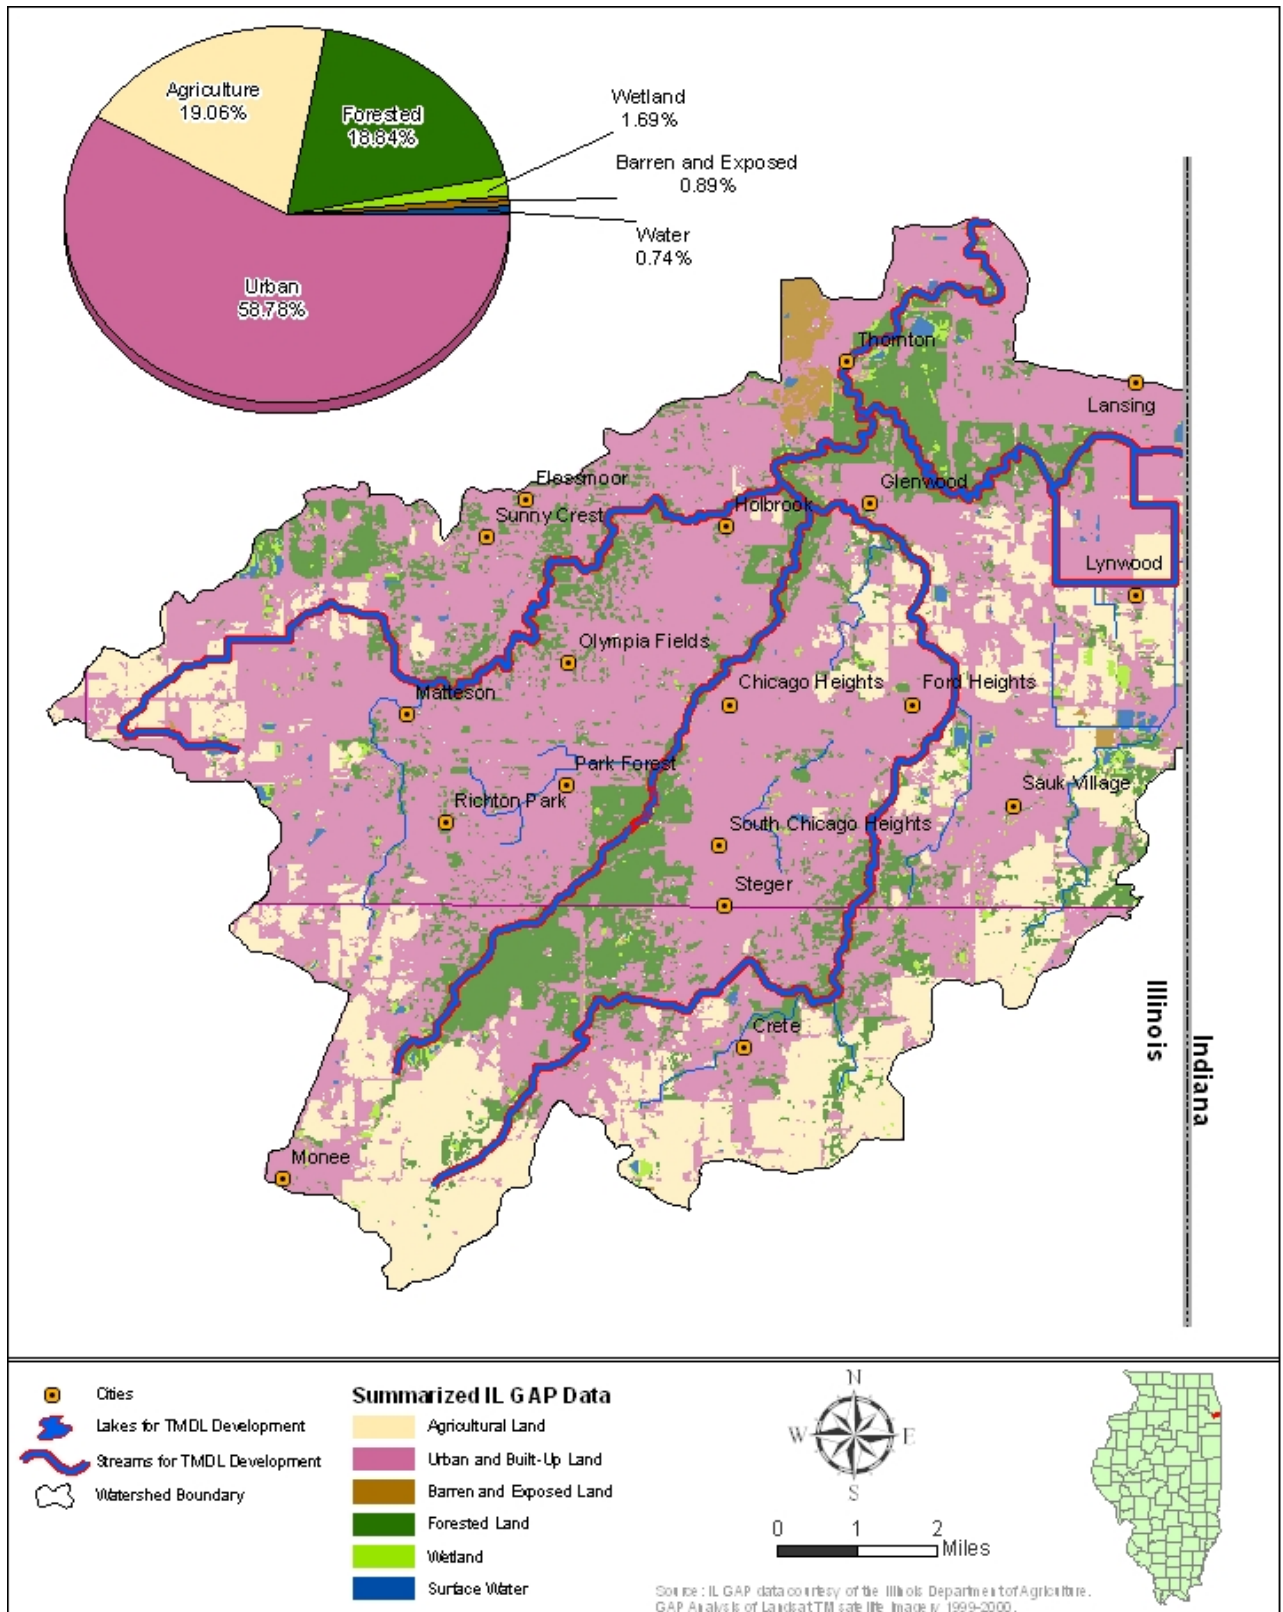

Current land use statistics for the Thorn Creek watershed were determined using IL-GAP data obtained from the Illinois Department of Agriculture (<http://www.agr.state.il.us/gis>). Today, the Thorn Creek watershed is over 58% Urban and built-up land and 19% agricultural. Forested Lands (including remnants of partial canopy/savannah mosaics) also comprise approximately 19% of the land usage. This is a slightly higher percentage than would be expected, as the entire state of Illinois as a whole reports only 11% forested lands, and is due largely to early purchases by both Will and Cook County Forest Preserves. About 2% of the land use is wetlands and surface waters represent less than 1% of the total land surface. A breakdown of land use classification types given in Table 2.2 and a map of current land uses is provided in Figure 2-4.

⁴ Thorn Creek Watershed Based Plan. 2005.

Table 2-2: Summary of IL-GAP Data for the Thorn Creek Watershed

IL GAP Classification	Acreage	Percent	Summary for Land Use Group
Urban and built-up land: Urban open space	17,100	25.5%	Urban and Built-Up 39,100 acres 58.8%
Urban and built-up land: Low/Medium density: Medium	14,000	20.8%	
Urban and built-up land: Low/Medium density: Low	4,000	6.4%	
Urban and built-up land: High density	4,000	6.1%	
Agricultural land: Corn	5,000	7.5%	Agricultural Land 12,768 acres 19.1%
Agricultural land: Soybeans	4,500	6.8%	
Agricultural land: Rural grassland	3,000	4.3%	
Agricultural land: Other small grains and hay	250	0.4%	
Agricultural land: Winter wheat	11	<0.1%	
Agricultural land: Other agriculture	7	<0.1%	
Forested land: Partial canopy/Savanna upland	4,700	7.1%	Forested Land 12,768 acres 18.8%
Forested land: Upland: Mesic	4,600	6.9%	
Forested land: Upland: Dry-Mesic	3,200	4.8%	
Forested land: Coniferous	16	<0.1%	
Wetland: Shallow marsh/Wet meadow	600	0.9%	Wetland 1,080 acres 1.7%
Wetland: Floodplain forest: Wet	250	0.4%	
Wetland: Floodplain forest: Wet-Mesic	100	0.2%	
Wetland: Shallow water	100	0.2%	
Wetland: Deep marsh	30	<0.1%

Figure 2-4: Thorn Creek Watershed Land Use Map

2.4 Soils

Soils data and Geographic Information Systems (GIS) files from the Natural Resources Conservation Service (NRCS) were used to characterize soils in the Thorn Creek watershed. General soils data and map unit delineations for the country are provided as part of the Soil Survey Geographic (SSURGO) database. Field mapping methods using national standards are used to construct the soil maps in the SSURGO database. Mapping scales generally range from 1:12,000 to 1:63,360; SSURGO is the most detailed level of soil mapping prepared by the NRCS. A map unit is composed of several soil series having similar properties. Identification fields in the GIS coverage can be linked to a database that provides information on chemical and physical soil characteristics. The SSURGO database contains many soil characteristics associated with each map unit. Of particular interest are the hydrologic soil group and the K-factor of the Universal Soil Loss Equation (USLE).

The SSURGO data was analyzed based on drainage class, hydrologic group and K-factor. The drainage class, as stated in the SSURGO database is, "...the natural drainage condition of the soil [which] refers to the frequency and duration of wet periods".⁵ Figure 2-5 exhibits the drainage classes of SSURGO data in the Thorn Creek watershed. However, some excessively drained areas can be found on the slopes near streams. These excessively drained areas may be in part due to the natural geology or pipes leading into the stream, built for anthropogenic outfalls. In general, however, the majority of the watershed is well drained.

The hydrologic soil group classification identifies soil groups with similar infiltration and runoff characteristics during periods of prolonged wetting. Typically, clay soils that are poorly drained have lower infiltration rates, while well-drained sandy soils have the greatest infiltration rates. The United States Department of Agriculture (USDA) has defined four hydrologic groups (A, B, C, or D) for soils. Type A soil has high infiltration while D soil has very low infiltration rate. Figures 2-6 show the distribution of hydrologic soil groups. Generally, areas to the east along the Indiana border have a moderately slow infiltration rate (hydrologic group C) with very poorly drained areas along the western border of the watershed. The central portion of the watershed is mostly hydrologic group B with a moderately high infiltration rate and corresponds to the well drained areas. Unfortunately, no data are available for some of central portions of the watershed.

A commonly used soil attribute of interest is the K-factor, a dimensionless coefficient used as a measure of a soil's natural susceptibility to erosion. Factor values may range from 0 for water surfaces to 1.00 (although in practice, maximum K-factor values do not generally exceed 0.67). Large K-factor values reflect greater potential soil erodibility.

The compilation of K-factors from the SSURGO data was done in several steps. Soils are classified in the SSURGO database by map unit symbol. Each map unit symbol is made up of components consisting of several horizons (or layers). The K-factor was determined by selecting the dominant components in the most surficial horizon for each map unit. The distribution of K-factor values in the Thorn Creek watershed is shown in Figure 2-7.

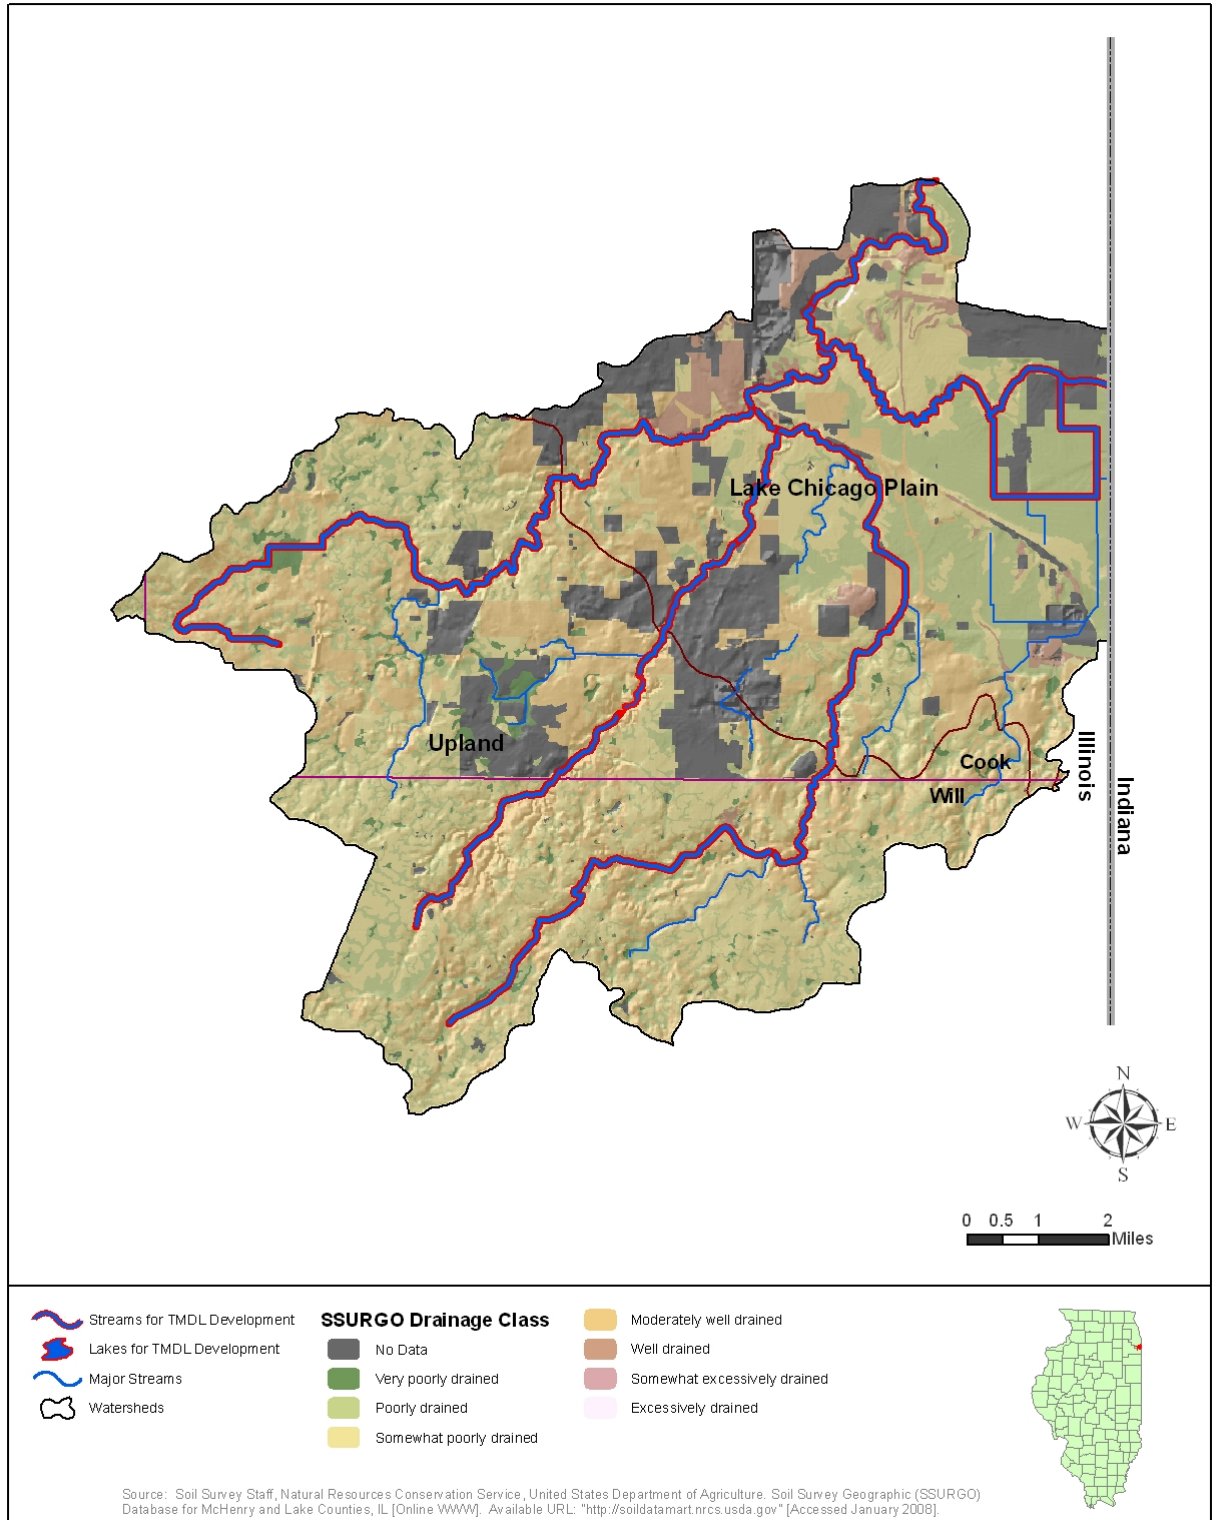

Figure 2-6: Thorn Creek Watershed SSURGO Hydrologic Group

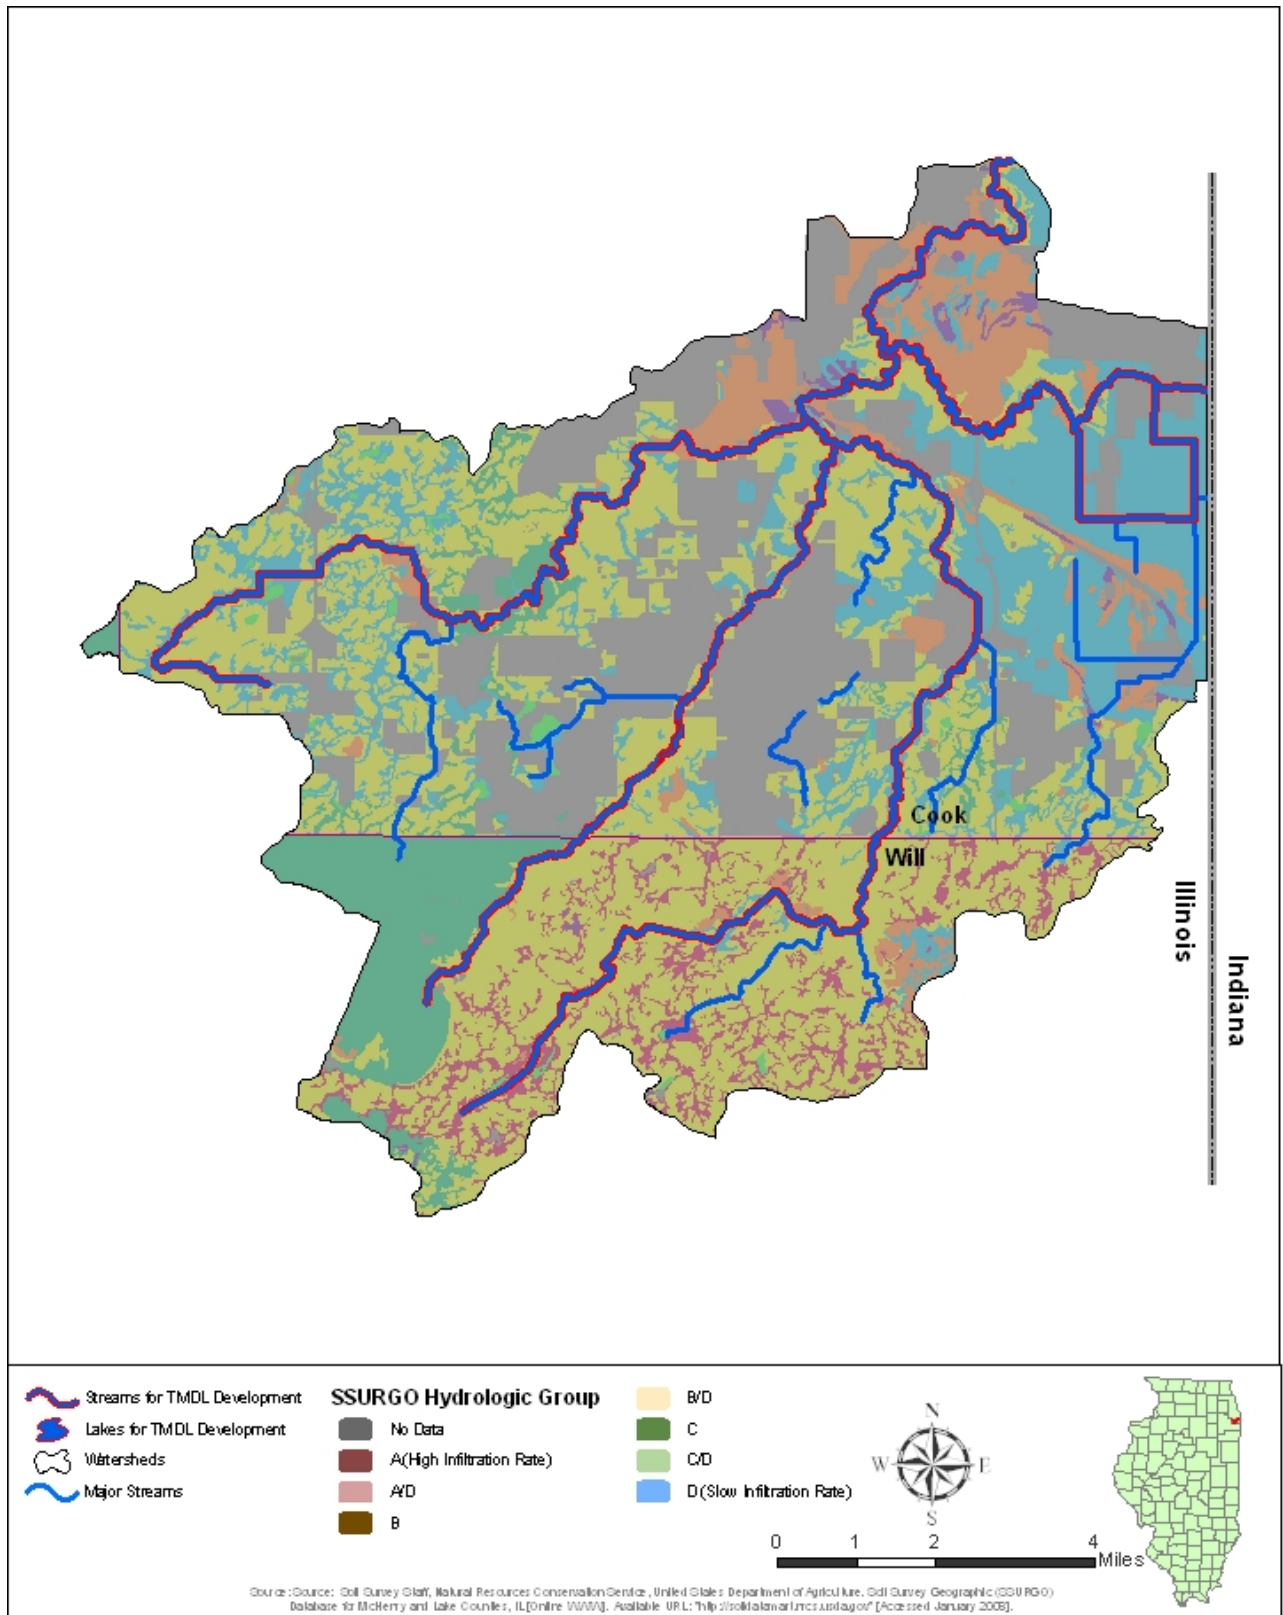

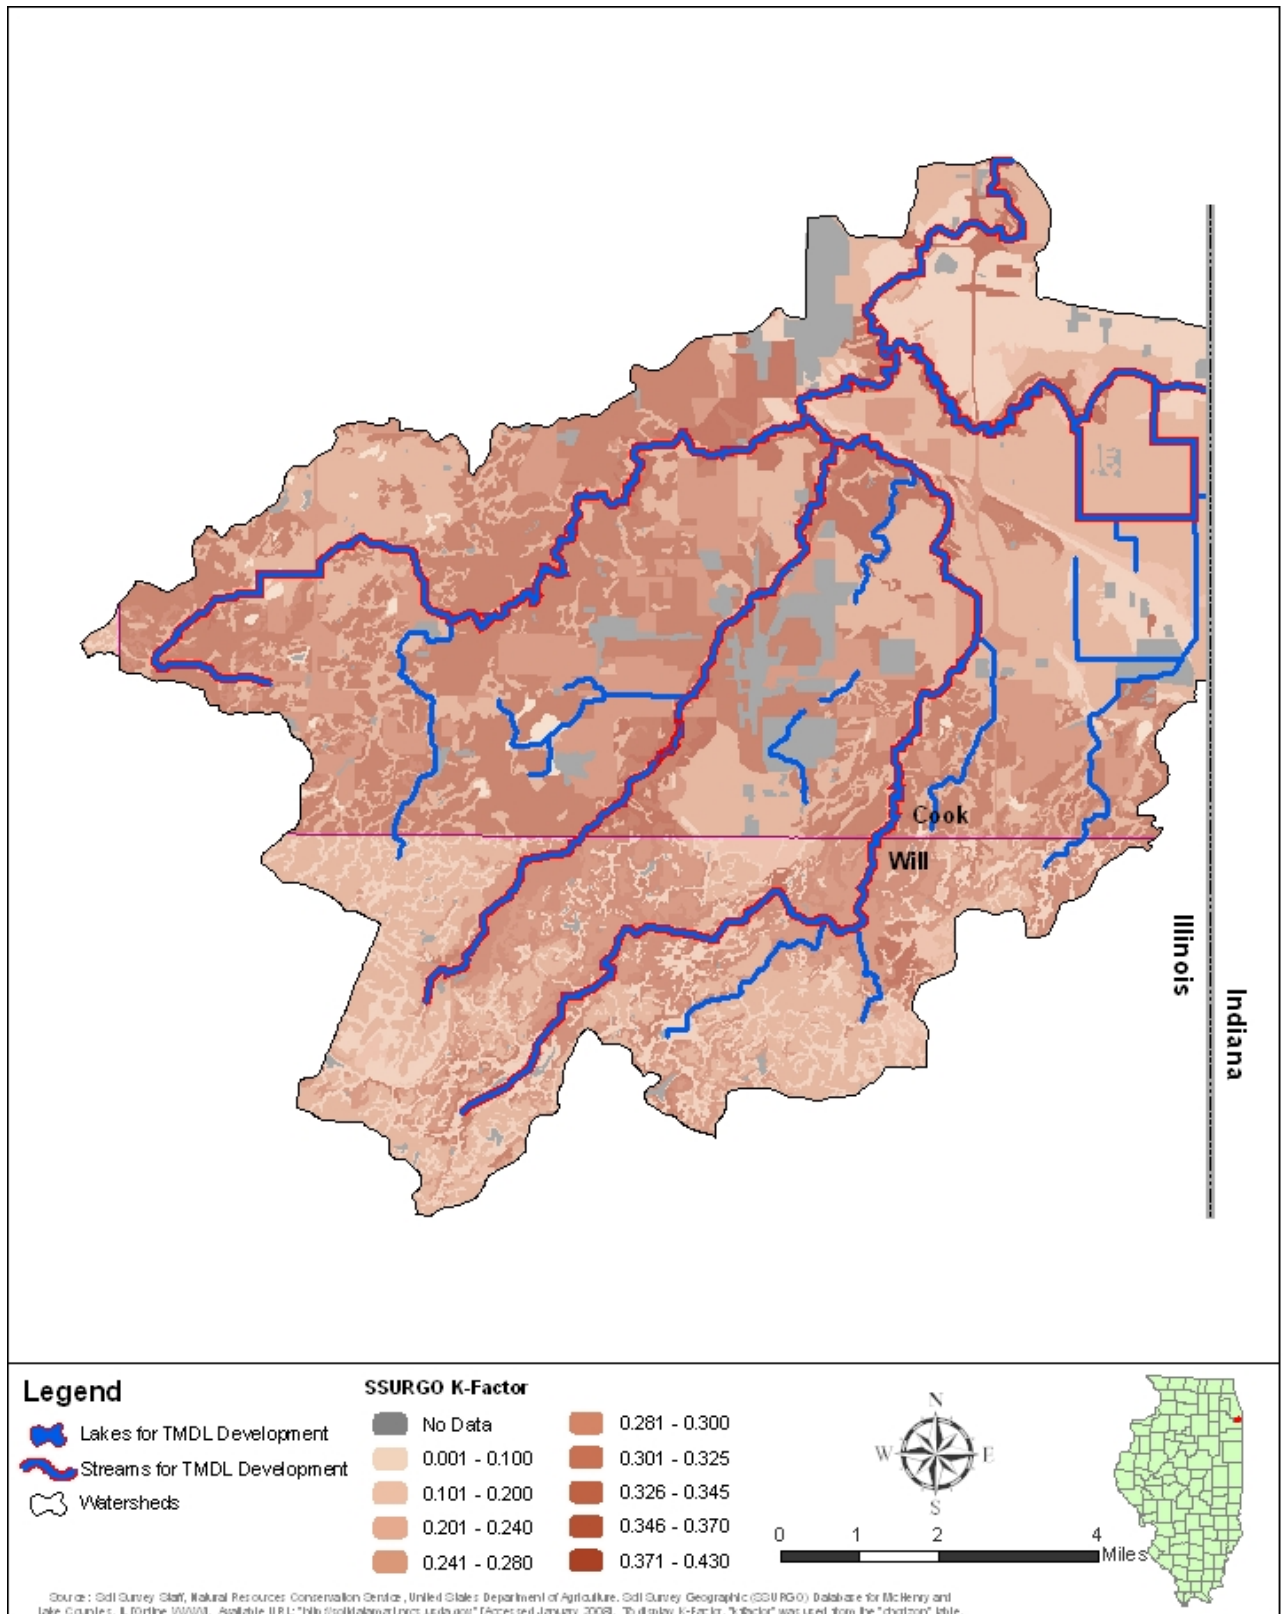

Figure 2-7: Thorn Creek Watershed SSURGO K-Factor

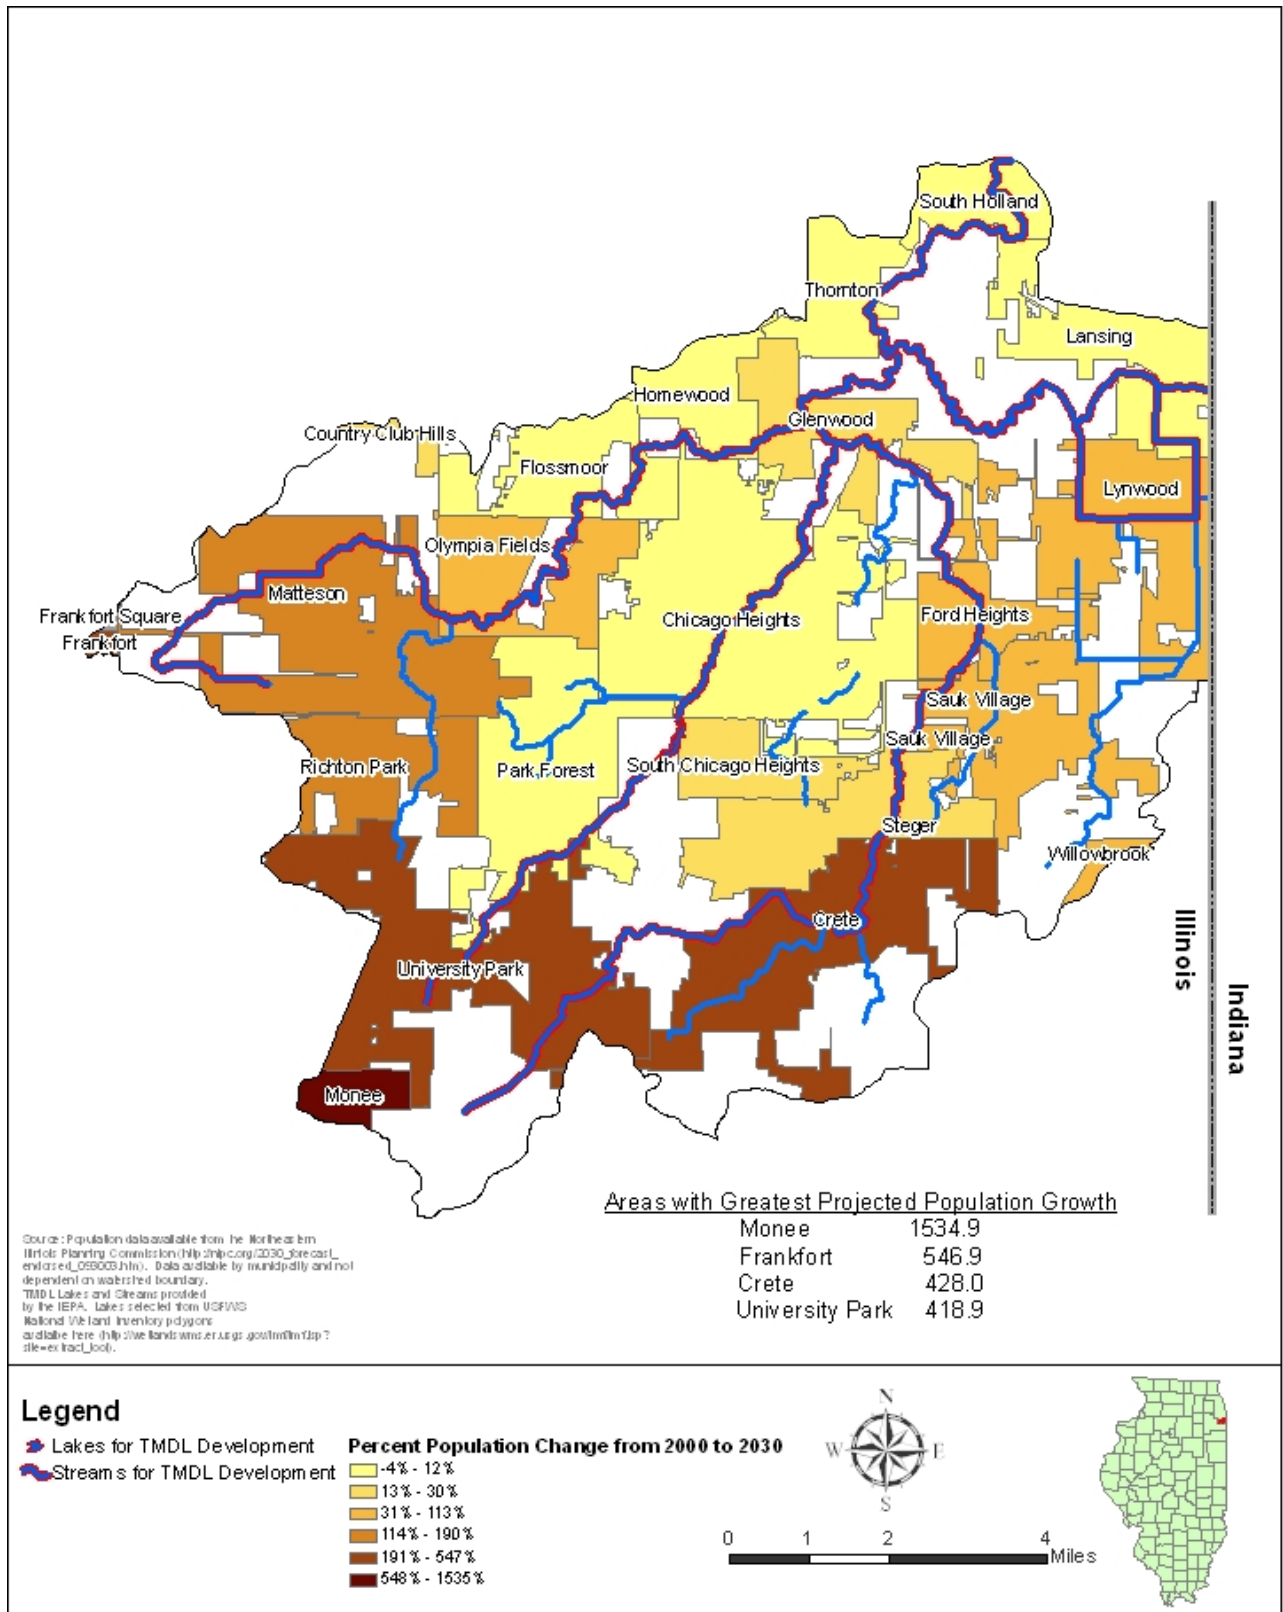

2.5 Population

Census 2000 data in format of TIGER/Line Shape file were downloaded to analyze the population in the Thorn Creek watershed. According to the 2000 Census, approximately 200,000 people reside in the Thorn Creek watershed; giving an average population density of about 1,900 people per square mile. Areas with the greatest population are in the north and central parts of the watershed including Chicago Heights, South Holland, Lansing and Park Forest.

Based on the Northern Illinois Planning Commission's (NIPC) 2030 forecasts (Figure 2-8), both Cook and Will counties are expected to increase their populations in the coming decades. Cook County is expected to increase by an estimated 10%. Will County is anticipated to rise from 500,000 to over a million, an estimated 114%. Although only about 1/3 of the watershed is in Will County, the impacts from such an increase are already underway as the once rural areas around Frankfort, Matteson, Richton Park and Monee develop new housing, undergo shopping mall redevelopments and light industry expansions. Predictions for Monee alone show over a 1,500% increase from 2000 census to 2030.

Figure 2-8: Thorn Creek Watershed Population Projection

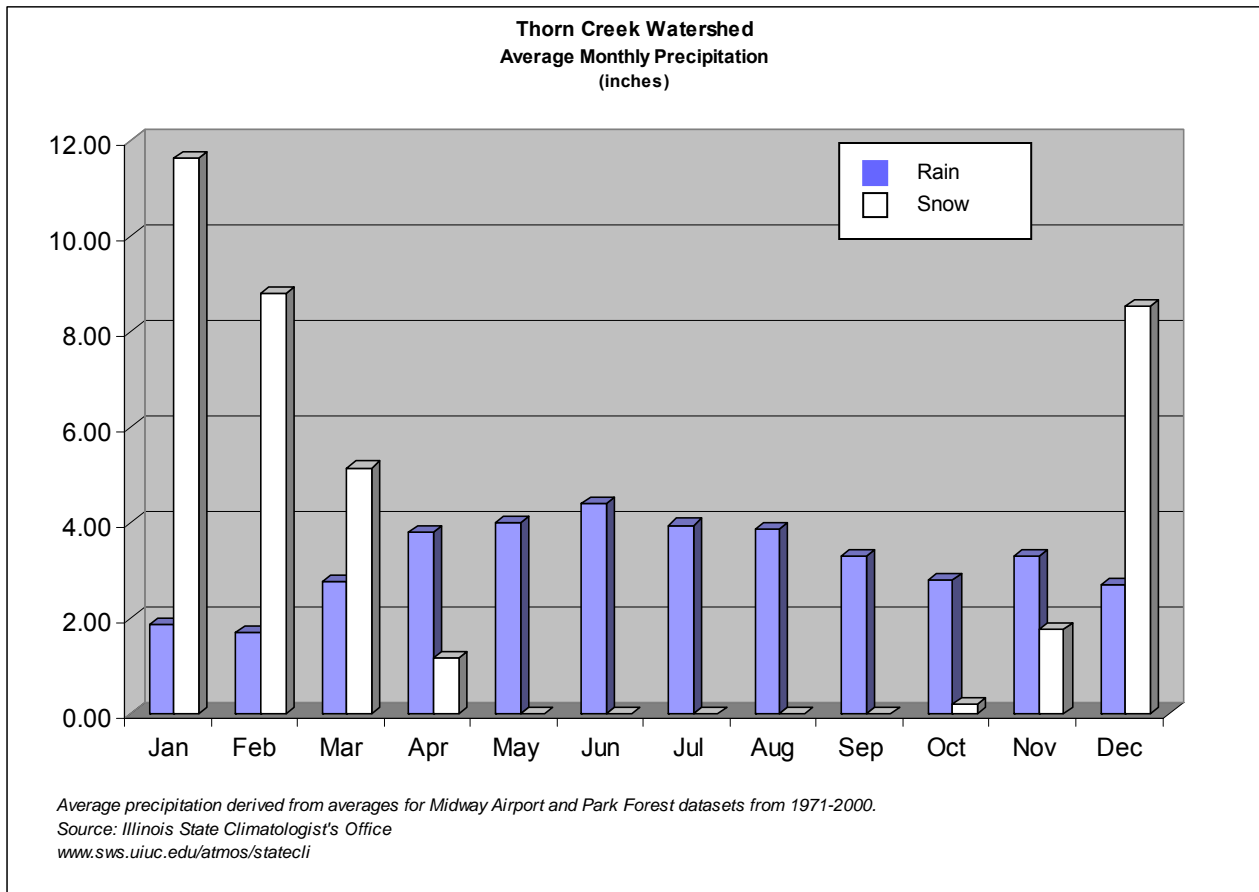

2.6 Precipitation

Northeastern Illinois has a continental climate with highly variable weather. The temperatures of continental climates are not buffered by the influence of a large waterbody (like an ocean, inland sea or Great Lake). Areas with continental climates often experience wide temperature fluctuations throughout the year. For Thorn Creek watershed, the highest temperatures in the summer can range from high 80s to over 100 degrees Fahrenheit and the lowest winter temperatures might range between sub-zero and the teens. The average temperatures, however, will range from the 20s in winter to the mid 70s in summer (Table 2-3). Precipitation in the form of rainfall is greatest in the growing season (April through September; Figure 2-9). Snow fall averages less than one foot in any given month⁶.

2.7 Hydrology

Understanding how water moves and flows is an important component of understanding a watershed. All of the parameters listed in the previous sections (i.e. topography, soils, and precipitation) impact hydrology. Hydrologic data are available from the USGS website⁷. The USGS maintains stream gages throughout the U.S. and they monitor conditions such as gage height, stream flow, and at some locations, precipitation.

Since 1948, the USGS has monitored seven stream gages along Thorn, Deer, Butterfield and North Creeks, as well as the Lansing Ditch system (Figure 2-10). All of these gages lie in the Lake Chicago Plain area in the northern third of the watershed. By 1948 this portion of the watershed already had urbanized development around the main channels; therefore, there is no baseline dataset that accurately reflects the natural flow conditions of the streams prior to their urbanization.

Analyses of monthly stream flow datasets presented in the 2005 Thorn Creek Watershed-based Management Plan show that the seasonal flow trend of the creeks follows the general precipitation pattern for the area: highest flows in April and the lowest flows in October. Base flow analysis, taking into consideration the influence of the Thorn Creek Basin Sanitary District, shows that apparent increases in base flow were due primarily to the wastewater treatment plant's (WWTPs) increased effluent flows, for those portions of Thorn

⁷ United States Geological Survey. 2008. www.usgs.gov. Website accessed September 2008.

Creek downstream of the WWTP in Chicago Heights. Effluent discharge increases from the Aqua of Illinois, University Park WWTP probably account for a similar pattern of increases in base flow for Deer Creek as well.

In 1979 the USGS abandoned many stream gages throughout the United States⁸. During this time, two Thorn Creek watershed gages were inactive; 05536210 (Thorn Creek near Chicago Heights, IL just upstream of the Thorn Creek Basin WWTP) and 05536270 (North Creek near Lansing IL). In the case of 05536210 (active only from 1965 to 1979), the Thorn Creek Basin WWTP is so close to the original gage site that the plant's own entry data makes the USGS gage effort repetitive. The gage at the western most confluence of the Lansing Ditch system with North Creek (05536270) showed an average difference of only seven cubic feet per second (cfs) from the gage at Lansing Ditch near Lansing, IL (05536265) for most of its 1948-1979 dataset. Around this same time, the peak flows for the gage at Lansing Ditch tend to remain between 100 and 250 cfs. Although it might be surmised that the overall measurements were redundant or that some regulating entity came on line at this time, no record remains with the USGS to explain its decision to abandon one gage over another.

The highest peak flow recorded for the gage at Lansing Ditch near Lansing, IL (05536265) was in July of 1957, at 4,700 cfs. The average peak flow for any given year was 190 cfs. The waters flowing from the Lansing Ditch system into North Creek and North Creek waters flowing from the east (including water from the Indiana portion of the watershed) enter the main stem of Thorn Creek above the Thorn Creek Basin WWTP. Although the mean annual flow fluctuates from year to year (depending on the annual precipitation) the average is about eight cfs with no apparent trend over time.

The gage on Deer Creek near Chicago Heights, IL (05536235) has operated continuously since 1948 (Figure 2-11). The highest peak flow recorded was also in July of 1957, at 1,380 cfs. The average peak flow for any given year is about 584 cfs. The only WWTP on Deer Creek is in University Park, about 2.5 miles from its headwaters. A quick look at the annual peak flows show that Deer Creek may have reacted to a regulation of its flow beginning around 1972: this coincides with the establishment of Aqua of Illinois' University Park WWTP. Deer Creek now shows its peak flows steadily between 400 and 900 cfs.

Butterfield Creek's gage (05536255 Butterfield Creek at Flossmoor), like the Deer Creek gage, has operated since 1948 (Figure 2-12). Its highest peak flow year was 2006 with 2,640 cfs. However, it must be noted that since 1992 all peak flows have carried the caveat that stream records are now affected by urbanization and channelization. A chart of the peak flow information from 1948 to the present shows increasing annual peak flow over time. The mean annual flow also shows an increasing trend over time, with a steeper rise occurring in the last 10 years (Figure 2-13). Butterfield Creek does not have a WWTP and the Frankfort, Matteson and Richton Park areas have converted agricultural lands to housing and shopping malls. The impermeable surfaces that have been added due to this development have contributed, in part, to an increase in runoff.

The main stem of Thorn Creek has datasets for three stream gages also stretching back to 1948. In 1979 the stream gage just upstream of the Thorn Creek Basin Sanitary District WWTP was made inactive. Currently, the main stem peak flows are being measured at a point just below the WWTP (05536215, Thorn Creek near Glenwood, IL) and have consistently shown a regulation by the WWTP (Figure 2-14). An examination of the peak flows recorded clearly show that, while higher annual peak flows are occurring, most peak flows remain between about 600 and 1,000 cfs. These recent data carry the caveat that the stream flows are affected by urbanization and channelization.

An additional stream gage, (05536275) Thorn Creek at Thornton, measures the Thorn Creek main stem flow after receiving the aggregate flow from Butterfield, Thorn, Deer, and North Creeks (including the Lansing ditch

⁸ Knapp, H.V. and M. Markus. 2003. Evaluation of the Illinois Streamflow Gaging Network. Prepared for the Illinois Department of Natural Resource.

system flow). These data include two or more peak flows for almost every year. When years containing two or more peak flow records are plotted for a maximum and minimum peak flow, the consistency of the minimum peak flow at around 1,000 cfs is clearly seen (Figure 2-14). The highest peak flow ever recorded is the July 1957 event also seen in the other creeks (4,700 cfs).

Over time, the Thorn Creek watershed as a whole may have higher high peak flows due to increasing urbanization, channelization and other reasons, but there is also more regulation of the stream flows by WWTPs and other uses.

3.0 Public Participation and Involvement

The IEPA is committed to keeping the watershed stakeholders and general public informed and involved throughout the TMDL process. Success for any TMDL implementation plan relies on a knowledgeable public to assist in follow-through required for attainment of water uses within their watershed. It is important to engage the local citizens as early in the process as possible by providing opportunities to learn and process information. This ensures that concerns and issues are identified at an early stage, so that they can be addressed and facilitate maximum cooperation in the implementation of the recommended courses of actions identified in the TMDL process. All stakeholders should have access to enough information to allay concerns, gain confidence in the TMDL process and understand the purpose and the regulatory authority or other responsible party that will implement recommendations.

IEPA, along with ENSR/AECOM, will hold up to two public meetings within the Thorn Creek watershed throughout the course of TMDL development. This section will be regularly updated following public meetings.

General information regarding the process of TMDL development in Illinois can be found at <http://www.epa.state.il.us/water/tmdl>. This link also contains paths to notice of public meetings and other TMDL-related watershed information for the entire state of Illinois.

Background learning about watersheds, watershed management, best management practices and the Clean Water Act (CWA) can be found on the EPA's water website at <http://www.epa.gov/watertrain/>.

For other reports and studies concerning the Thorn Creek watershed please visit the Illinois Rivers Decision Support System: Chicago/Calumet River watershed Investigation website: <http://ilrdss.sws.uiuc.edu/>. The website contains reports, data and additional links to other sources specifically related to this watershed.

4.0 Water Quality Standards and TMDL Targets

Water pollution control programs are designed to protect the beneficial uses of the water resources within the state. Each state has the responsibility to set water quality standards that protect these beneficial uses, also called “designated uses.” Illinois waters are designated for various uses including aquatic life, wildlife, agricultural use, primary contact (e.g., swimming, water skiing), secondary contact (e.g., boating, fishing), industrial use, drinking water, food-processing water supply and aesthetic quality. Illinois’ WQS provide the basis for assessing whether the beneficial uses of the state’s waters are being attained.

4.1 Illinois Pollution Control Program

The Illinois Pollution Control Program (IPCB) is responsible for setting WQS to protect designated uses. The IEPA is responsible for developing scientifically based water quality criteria and proposing them to the IPCB for adoption into state rules and regulations. The Illinois WQS are established in the Illinois Administrative Rules Title 35, Environmental Protection; Subtitle C, Water Pollution; Chapter I, Pollution Control Board; Part 302, Water Quality Standards. The federal CWA requires states to review and update WQS every three years. IEPA, in conjunction with U.S. EPA, identifies and prioritizes those standards to be developed or revised during this three-year period. The IPCB has established four primary sets (or categories) of narrative and numeric WQS for surface waters.

4.2 Designated Uses

The waters of Illinois are classified by designated uses, which include: General Use, Public and Food Processing Water Supplies, Lake Michigan, and Secondary Contact and Indigenous Aquatic Life Use⁹. The only waterbody classification applicable to the Thorn Creek watershed is the General Use classification.

General Use standards, as defined by IPCB, will protect the state's water for aquatic life, wildlife, agricultural use, secondary contact use and most industrial uses and ensure the aesthetic quality of the state's aquatic environment. Primary contact uses are protected for all General Use waters whose physical configuration permits such use.

4.3 Applicable Illinois Water Quality Standards

To make 303(d) listing determinations for aquatic life uses, IEPA first collects biological data and if these data suggest that impairment to aquatic life exists then a comparison of available water quality data with WQS occurs. Table 4-1 summarizes the applicable water quality standards for the Thorn Creek watershed.

⁹ Illinois Environmental Protection Agency (IL EPA), Bureau of Water, Illinois Integrated Water Quality Report and Section 303(d) List – 2008 (draft), Water Resources Assessment Information and Listing of Impaired Water, March.

Table 4-1: Applicable Water Quality Standards for the Thorn Creek Watershed

Parameter	Units	General Use Water Quality Standard
Chloride - Dissolved	mg/L	500*
Copper - Dissolved	mg/L	Acute – 0.07** Chronic – 0.04**
Dissolved Oxygen (above thermocline in thermally stratified waters or entire water column in unstratified waters)	mg/L	March – July 5.0 instantaneous minimum 6.0 as daily mean averaged over 7 days August – February 3.5 instantaneous minimum 4.0 as daily mean averaged over 7 days 5.5 as daily mean averaged over 30 days
Fecal Coliform	cfu/100 ml	200 geometric mean based on a minimum of 5 samples taken over any 30 day period; 400 maximum not to be exceeded in more than 10% of samples taken during any 30 day period.
pH	s.u.	6.5 – 9.0 except for natural causes
Phosphorus - Total	mg/L	0.05 in any reservoir or lake with a surface area of at least 20 acres or in any stream at the point where it enters any such lake or reservoir
Silver - Total	µg/L	5.0*
Zinc - Dissolved	µg/L	Acute – 336.6** Chronic – 64.6**

*Indicates protection of Human Health criteria.

**Standard is based on the average ambient hardness of the waterbody.

4.4 TMDL Targets

In order for a water body to be listed as Full Support, it must meet all of its applicable designated uses. Because WQS are designed to protect those designated uses, a pollutant's numeric WQS is therefore used as the target or endpoint for establishing a TMDL. Table 4-2 summarizes the targets that will be used in the TMDL development for the Thorn Creek watershed.

Table 4-2: TMDL Targets for Impaired Waterbodies in the Thorn Creek Watershed

Segment ID	Waterbody Name	Impairment	TMDL Target	Units
IL_HBD-02	Thorn Creek	Dissolved Oxygen	>5.0 Mar-Jul, >3.5 Aug-Feb	mg/L
		Fecal Coliform	<200	cfu/100 ml
		Silver	<5.0	µg/L
		Zinc	<64.6	µg/L
IL_HBD-03	Thorn Creek	Dissolved Oxygen	>5.0 Mar-Jul, >3.5 Aug-Feb	mg/L
		Fecal Coliform	<200	cfu/100 ml

		Total Phosphorus	0.05	mg/L

5.0 Water Quality Assessment

Data were collected and reviewed from many sources in order to further characterize the Thorn Creek watershed. Data have been collected from surface waters and point and nonpoint sources. This information is presented and discussed in further detail throughout the remainder of this section.

5.1 Water Quality Data

The Thorn Creek watershed has 12 impaired segments within its drainage area, 10 of which are targeted for TMDL development. Available data used for assessing these waterbodies originated from 24 water quality stations within the Thorn Creek watershed. Figure 5-1 shows the water quality data stations within the watershed that contain data relevant to the impaired segments.

Data used for analysis are a combination of both legacy and modernized U.S. EPA Storage and Retrieval (STORET) databases, Thorn Creek Sanitary District data, Metropolitan Water Reclamation District of Greater Chicago (MWRDGC) data, and IEPA database data. The compiled database ranges from 1957 through 2007.

Data relevant to impairments were compiled for each impaired waterbody and summarized. The following parameters are grouped by impairment and discussed in relation to the relevant Illinois numeric WQS. For all assessments, compliance is determined at the surface of a stream or at the one-foot depth from the lake surface.

5.1.1 Dissolved Oxygen

The distribution of DO concentrations for each segment in the Thorn Creek watershed are presented in Figure 5-2. The water quality standard for DO includes a seasonal component. From March through July the instantaneous minimum is 5.0 mg/L, and the daily mean averaged over seven days must not be less than 6.0 mg/L. From August through February the instantaneous minimum is 3.5 mg/L, the daily mean averaged over seven days must not be less than 4.0 mg/L, and the daily mean averaged over 30 days must not be less than 5.5 mg/L. Data used for assessments ranged from 1959 to 2007.

5.1.2 Fecal Coliform

The distribution of fecal coliform for each impaired segment in the Thorn Creek watershed is presented in Figure 5-3. The WQS for fecal coliform is a 200 cfu/100ml geometric mean based on a minimum of five samples collected over any 30 day period or a 400 cfu/100ml maximum not to be exceeded in more than 10% of samples collected during any 30 day period. Due to the unlikelihood of having five fecal coliform samples per month upon which to judge compliance, a single exceedance of 400 cfu/100 ml is often interpreted as an instantaneous maximum. Data used for assessments ranged from 1970 to 2007.

5.1.3 Total Phosphorus

Compliance with the total phosphorus standard is based on samples collected at a one foot depth from the surface. The water quality standard for total phosphorus is a maximum concentration of 0.05 mg/L and is applicable only to lakes with a surface area of 20 acres or greater. The only impaired lake within the Thorn Creek watershed is Sauk Trail. Data, however, were not available for analysis.

Figure 5-1: Monitoring Stations Used for Assessing Impairments

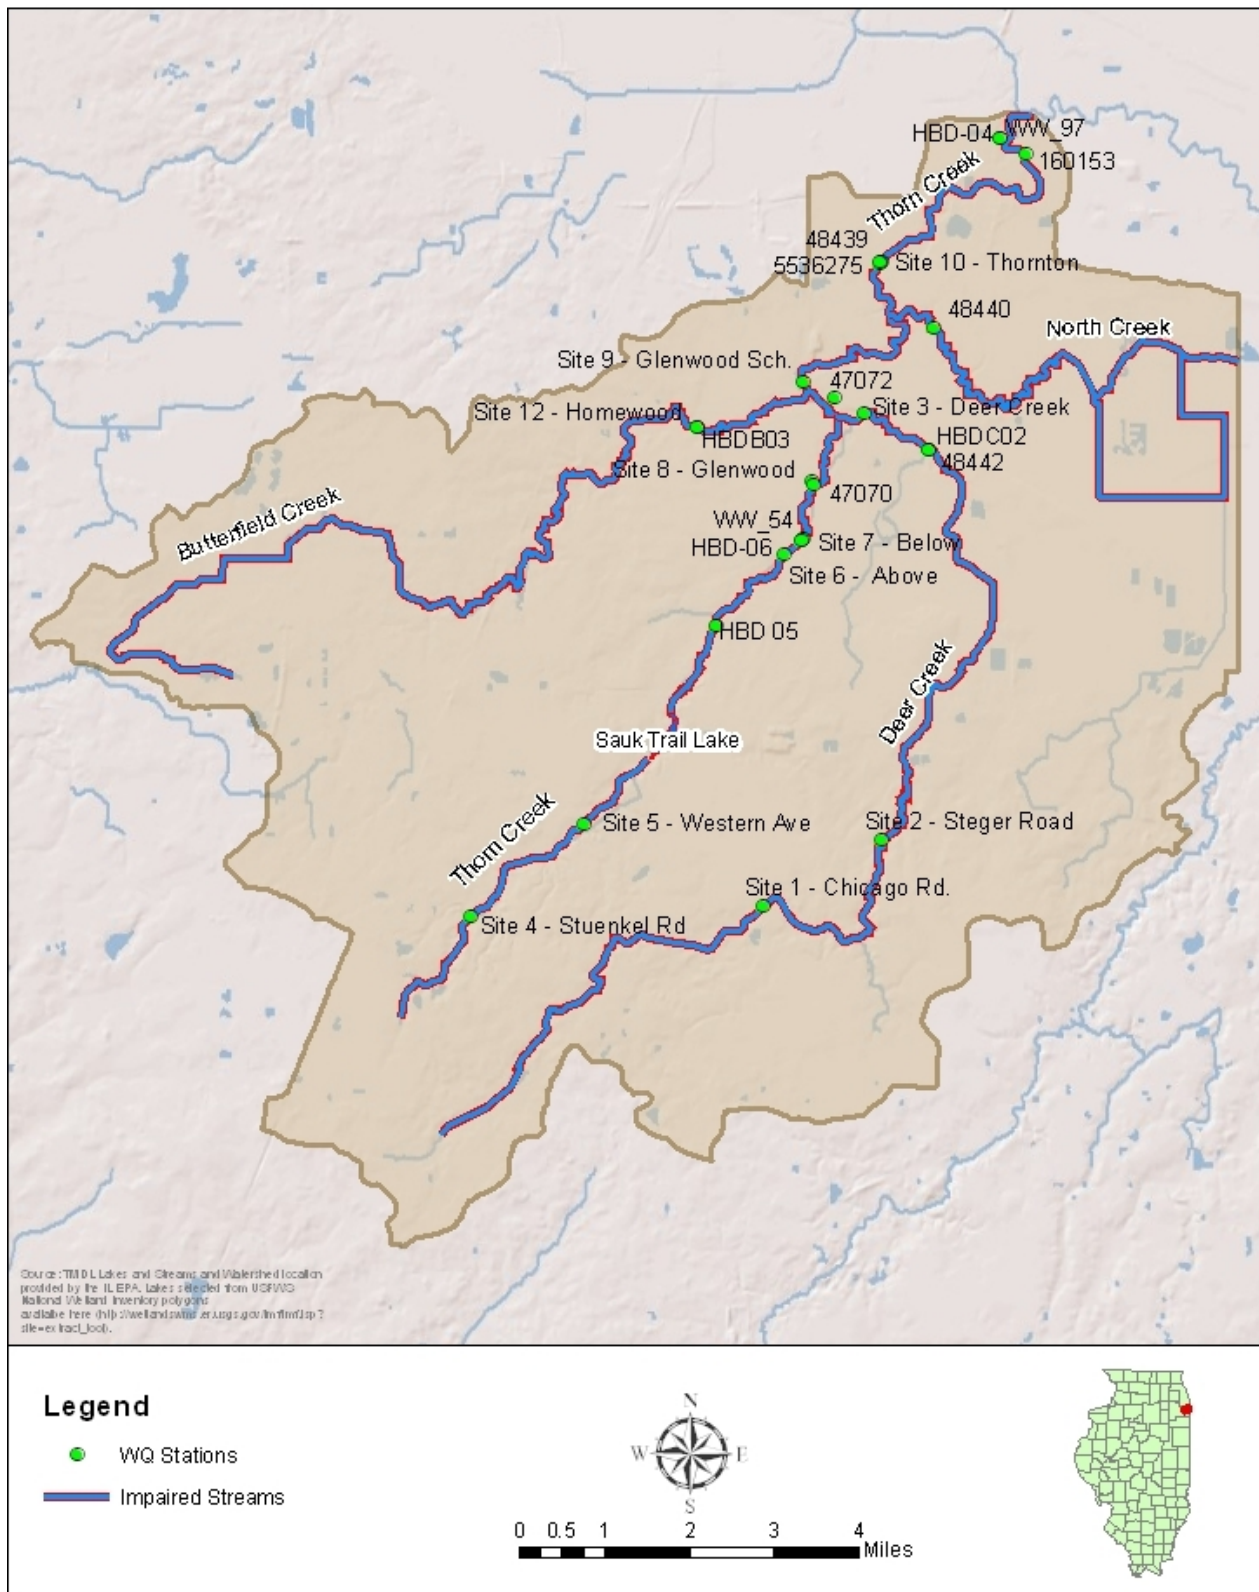

Figure 5-2: Dissolved Oxygen Distribution 1959-2007

Figure 5-3: Fecal Coliform Distribution 1970-2007

5.1.4 pH

The average pH values for each impaired segment within the Thorn Creek watershed are presented in Table 5-1 and Figure 5-4. The WQS dictates an acceptable pH range between 6.5 and 9 standard units (s.u.). Data used for analysis ranged from 1957 to 2007 at HBD04 and from 1973 to 2007 at HBD06.

Table 5-1: pH Data Summary 1957-2007

Segment	Units	# Observations	# Violations	Min	Max
IL_HBD-04	s.u.	335	3	6.1	9
IL_HBD-06	s.u.	262	2	6.2	8.5

Figure 5-4: pH Time Series for IL_HBD-04 and IL_HBD-06

5.1.5 Copper

The IL_HBD-04 segment of Thorn Creek is the only segment impaired for copper. State language dictates that acute and chronic WQS apply to dissolved copper and that each must be calculated based on ambient hardness values. The acute and chronic standards were calculated to be 0.07 and 0.04 mg/L respectively based on an average ambient hardness value of 549 mg/L. Table 5-2 summarizes the average copper values for IL_HBD-04. However, available data (2001 – 2004) suggest that no copper impairment exists (Figure 5-5).

Table 5-2: Copper Data Summary 2001-2004

Segment	Units	# Observations	# Violations	Min	Max	Average	Median	Standard Deviation
HBD04	mg/L	73	N/A	0	0.03	0.005	0.000	0.007

Figure 5-5: Copper Time Series for IL_HBD-04

5.1.6 Chloride

Chloride exceedances were only recorded in the IL_HBD-04 segment of Thorn Creek. Table 5-3 and Figure 5-6 summarize the average copper values for IL_HBD-04. The general use WQS for chloride is 500 mg/L and dates for available data used for assessment ranged from 1957 to 2005.

Table 5-3: Chloride Data Summary 1957-2005

Segment	Units	# Observations	# Violations	Min	Max	Average	Median	Standard Deviation
IL_HBD-04	mg/L	171	4	50	753	239	222	113

Figure 5-6: Chloride Time Series at IL_HBD-04

5.1.7 Silver

Table 5-4 and Figure 5-7 summarize total silver values within IL_HBD-02 and IL_HBD-04, the only two segments where silver exceedances were recorded. HBD02 and HBD04 violated the silver WQS of 5 µg/L six and five times, respectively. Data used for analysis ranged from 1980 to 1998 at IL_HBD-02 and from 2001 to 2007 at IL_HBD-04.

Table 5-4: Silver Data Summary 1980-2007

Segment	Units	# Observations	# Violations	Min	Max	Average	Median	Standard Deviation
HBD02	µg/L	272	6	0	40	2.52	3.00	3.3
HBD04	µg/L	83	5	0	40	1.91	0.00	4.9

Figure 5-7: Silver Time Series at IL_HBD-02 and IL_HBD-04

5.1.8 Zinc

Zinc exceedances were only recorded in the IL_HBD-02 segment of Thorn Creek (Table 5-5, Figure 5-8). Similar to copper acute and chronic water quality standards only apply to dissolved zinc and each must be calculated based on ambient hardness values. The acute and chronic water quality standards for zinc were calculated to be 336 and 64 µg/L respectively using an average ambient hardness value of 385 mg/L. Dates for available data at IL_HBD-02 ranged from 1981 to 2004.

Table 5-5: Zinc Data Summary 1981-1998

Segment	Units	# Observations	# Violations	Min	Max	Average	Median	Standard Deviation
IL_HBD-02	µg/L	214	83	0	158	59.6	50	35.2

Figure 5-8: Zinc Time Series at IL_HBD-02

5.2 Point Sources

A number of point source dischargers actively maintain National Pollutant Discharge Elimination System (NPDES) permits within the Thorn Creek watershed. Discharge Monitoring Reports (DMRs) for each discharger will be required for the Stage 3 analysis of the TMDL, as available data will be quantified and analyzed to determine the point source loading for each receiving water. Table 5-6 lists the existing NPDES permits as provided by EPA’s Enforcement Compliance History Online (ECHO) database. Geographic locations are provided in Figure 5-9.

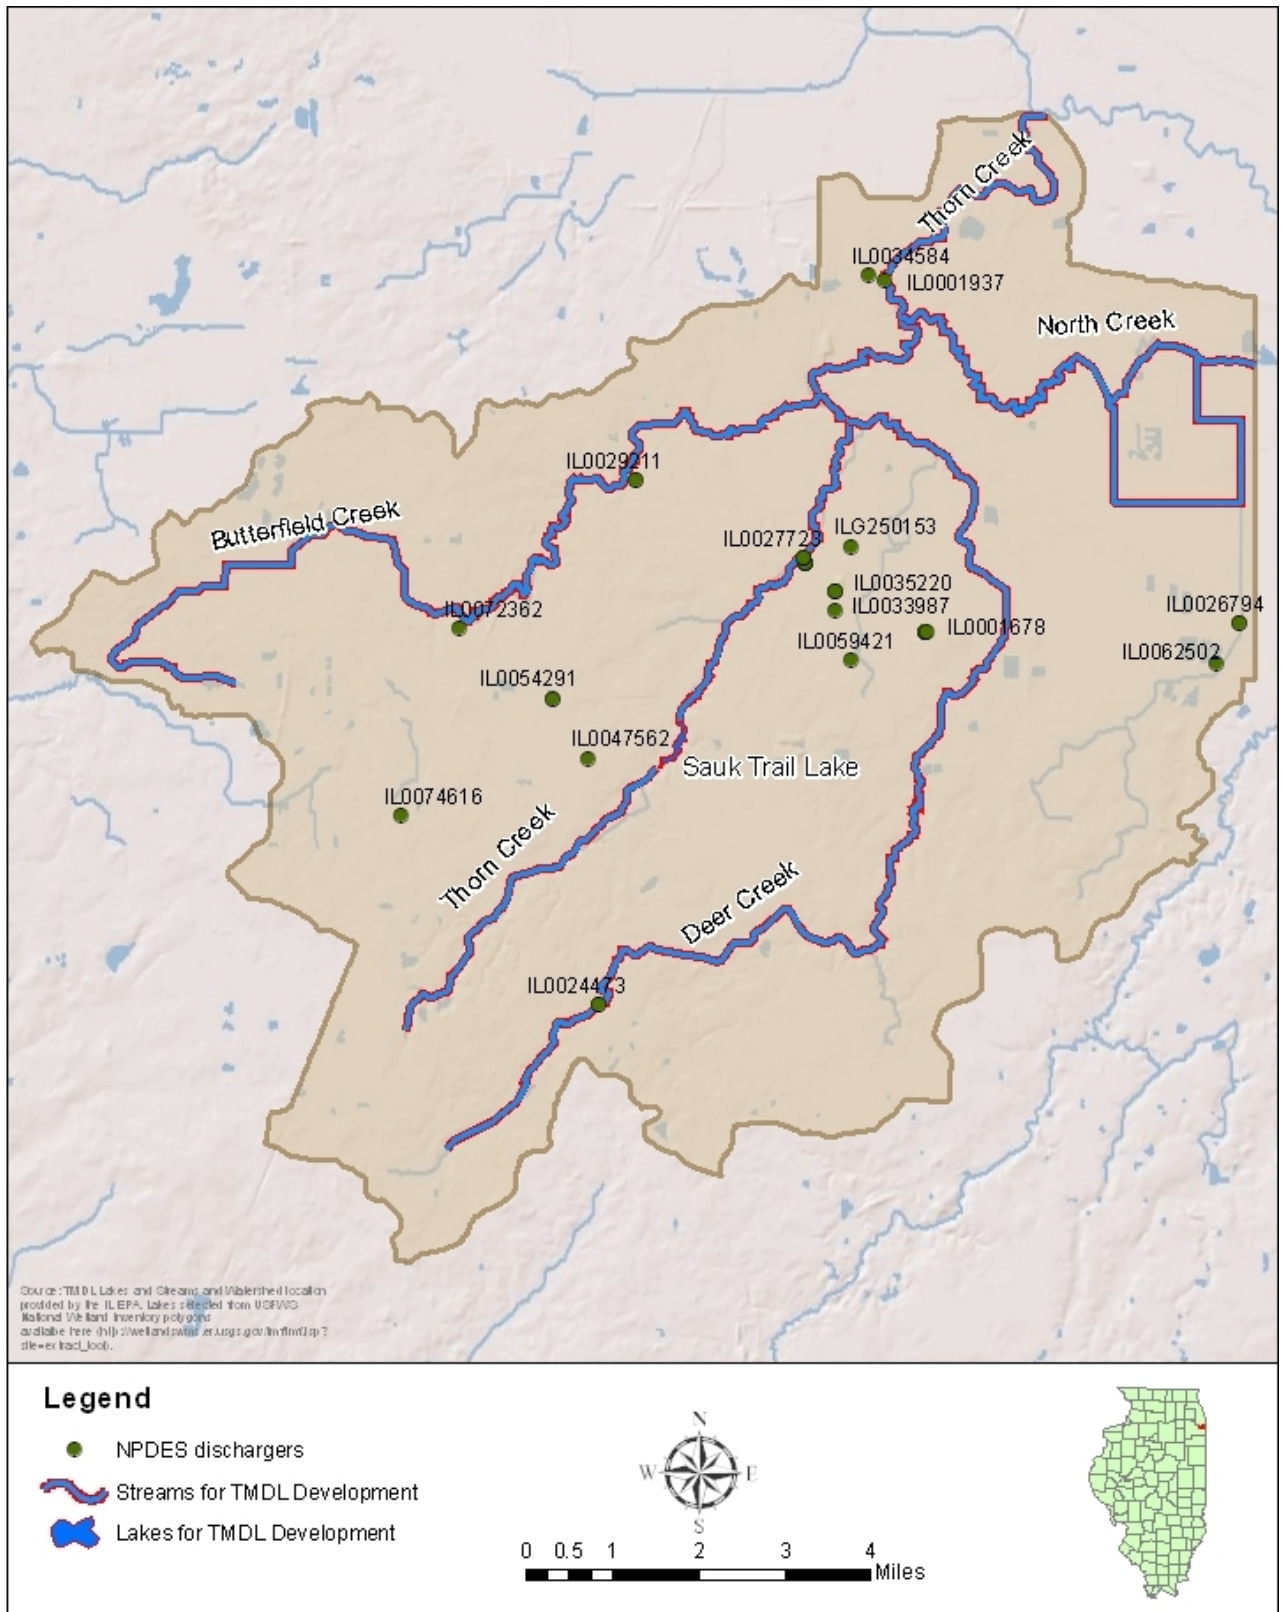

Table 5-6: Existing NPDES Dischargers in the Thorn Creek Watershed

Figure 5-9: Existing NPDES Dischargers in the Thorn Creek Watershed

5.3 Non-Point Sources

The Thorn Creek watershed is dominated by urban growth; current land use is approximately 60% urban. Further, almost 20% of the remaining land use is considered agricultural, a primary source of non-point source pollution in waterbodies. To properly manage and maintain water quality in the Thorn Creek watershed, the impacts associated with new development and agriculture must be carefully evaluated.

Urban and suburban development can adversely impact water quality in a number of ways. During the construction phase of development, soils destabilized as a result of clearing, grading, and excavation are subject to increased erosion by wind and water. These eroded soils can be carried offsite and deposited in receiving waters such as lakes, rivers and wetlands. Adverse impacts associated with such sediment loading include increased turbidity and habitat modification, including smothering of invertebrates and covering spawning beds. Typically, the construction phase is relatively short-lived; however, the impacts to receiving waters from poorly managed construction activities may be extremely severe and the effects can endure long after the project is over.

Post-construction receiving water quality impacts may become more pronounced due to potentially dramatic changes to the area's hydrology (reduced baseflow and exaggerated peak flow volumes), and the change in land use compared to predevelopment conditions. The increase in impervious areas, such as roadways and parking lots, can often result in increased runoff rates and volumes. This can result in increased streambank erosion which can lead to increased sediment loading and its associated water quality problems. The increased runoff can also accelerate the transport of land-borne pollutants such as heavy metals, oil and grease, pesticides, fertilizers and other nutrients, and toxic organic contaminants. Increased imperviousness can also cause significant elevations in receiving water temperatures during summer months. Winter road deicing activities can contribute high levels of chlorides or sediment.

Agricultural practices in the Thorn Creek watershed can also adversely impact water quality. The dominant crops found in the watershed are corn (40%) and soybean (35%), but other harvested crops include winter wheat, grain, and hay. Fertilizers used for such crops typically consist of nitrogen and phosphorus and are considered a potential source of nutrient enrichment in waterbodies.

Water quality impacts may be evaluated in terms of short-term impacts, and long-term impacts. Individual runoff events can cause short-term impacts to receiving waters, and are typically on a timescale of hours to days. Changes to the dry and wet weather hydrology, streambank morphology, and water chemistry of the receiving water are considered long-term impacts. Such long-term chemical impacts are most critical for those waters with longer residence times such as lakes and wetlands, and slow-moving stream segments. With regards to urban development and agriculture, pollutant concentrations are best used to evaluate short-term effects, while pollutant loadings are appropriate for assessing long-term impacts. Thorn Creek watershed planners and developers need to understand these impacts and carefully plan in order to mitigate the negative water quality impacts of development and agriculture.

6.0 TMDL Approach and Data Needs

This chapter discusses the methodology that may be used for the development of TMDLs for the Thorn Creek watershed. While a detailed watershed modeling approach can be advantageous, a simpler approach is often able to efficiently meet the requirements of a TMDL and yet still support a TMDL-guided and site-specific implementation plan. The final selection of a methodology will be determined with consultation with the IEPA based on following factors:

- Fundamental requirements of a defensible and approvable TMDL
- Data availability
- Fund availability
- Public acceptance
- Complexity of water body

A simpler approach shall be used as long as it adequately supports the development of a defensible TMDL. If it is deemed that this approach will not suffice, a more sophisticated modeling approach will be recommended for analysis to help better establish a scientific link between the pollutant sources and the water quality indicators for the attainment of designated uses. Methodology for estimating daily loads will depend on available data as well as the selected analysis.

6.1 Recommended Modeling Approach for Fecal Coliform

Many states currently use load duration curves for fecal coliform TMDLs for its simplicity and effectiveness. Load duration curves use water quality criteria, ambient concentrations, and observed flows to estimate loading capacities for streams under various flow conditions.

The first step in this process is to obtain an appropriate stream flow record. This is often difficult for streams not monitored by the USGS. There are methods, however, for developing streamflow statistics on ungaged streams. Regional curve numbers and regression equations are typically used in such instances. Alternatively, a gaged reference watershed can be used to obtain a streamflow record.

Flow duration curves are developed from streamflow records spanning multiple decades. The flow duration curve is based on flow frequency which provides a probability of meeting or exceeding a given flow. The duration curve is broken into hydrologic categories where high flows represent a duration interval of 0-10%, moist conditions represent 10-40%, mid-range flows 40-60%, dry conditions 60-90% and low flows 90-100%.

Once the flow duration curve is established, a load duration curve can be generated by multiplying streamflow with the numerical water quality standard and a conversion factor to obtain the load per day for a given streamflow. Individual measurements can be plotted against the load duration curve to evaluate patterns of impairment. Values that fall above the load duration line indicate an exceedance of the daily load and hence, water quality standard. These data can aid in determining whether impairment occurs more frequently in one of the hydrologic categories (wet, moist, mid-range, dry or low).

The margin of safety (MOS) for duration curves can be implicit or explicit. Implicit MOS are derived from the inherent assumptions in establishing the water quality target. Explicit MOS include setting the water quality target lower than the WQS or not allocating a portion of the allowable load. For the Thorn Creek TMDL, an explicit MOS of 5% lower than the WQS is proposed. The standard of 400 col/100ml not to exceed 10% of the samples in a 30-day period will be used, and thus the standard used to generate the load duration curve will be 380 col/100ml.

Wasteload allocations (WLA) will be based on NPDES permit limits. Average discharge flow and permit limits will be used to calculate a daily load and serve as the WLA. WLAs for NPDES-permitted stormwater discharges, including current and future Municipal Separate Storm Sewer Systems (MS4s), “Urbanized” areas, construction and industrial discharges and sanitary sewer overflows (SSOs) that do not have numerical effluent limitations will be expressed as a percent reduction instead of a numerical target. The NPDES Phase II Stormwater Regulations require all areas defined as “Urbanized” by the US Census obtain a permit for the discharge of stormwater. Stormwater discharges are required to meet the percentage reduction or the existing instream standard for the pollutant of concern, whichever is less restrictive. The load allocation (LA) for all non-regulated sources, including non-point sources, will also be expressed as a percent reduction. The percent reduction is based on the maximum reduction required to meet WQS plus a margin of safety under critical conditions.

The critical condition for fecal coliform load duration TMDLs is established by hydrologic category. It is defined as the greatest reduction needed to meet WQS among all hydrologic categories. For example, if an 89% reduction is required to meet the TMDL under wet conditions and a 50% reduction is required under dry conditions, an 89% reduction will be required under all hydrologic conditions to ensure that the TMDL is protective under all hydrologic conditions.

Seasonality of loading will also be evaluated. Flow duration intervals will be plotted by month to determine if there is a strong seasonal component. Although this will not change allocations, this may assist in implementation planning.

6.2 Recommended Modeling Approach for Dissolved Oxygen

QUAL-2K, a spreadsheet model that is based on the fundamental Streeter-Phelps DO sag equation, is recommended for DO TMDL development for impaired waterbodies in the Thorn Creek watershed. QUAL-2K is a one-dimensional, steady-state model that can accommodate point and non-point source loading and is capable of modeling DO in streams and well-mixed lakes. QUAL-2K is an updated version of QUAL-2E and has been developed using a Microsoft Excel interface. QUAL-2K allows for model segmentation, the use of two forms of carbonaceous BOD (both slow and rapid oxidizing forms), and is also capable of accommodating anoxia and sediment – water interactions. While the model is simplistic in nature, it is capable of estimating critical BOD concentrations associated with instream DO concentrations of 5 mg/L.

If sufficient data are available, load duration curves could also be used to adequately simulate BOD loading associated with DO sags in streams. These calculated loads will be the basis for recommending TMDL reductions if necessary.

6.3 Recommended Modeling Approach for Total Phosphorus

Ongoing sampling at Sauk Trail will provide data to be used for TMDL development. An export coefficient model linked to empirical in-lake response models will be used to determine existing loading and load reductions required to bring Sauk Trail into compliance with current WQS. This model, ENSR-LRM (lake response model), was developed by ENSR and has been used on more than 35 lake TMDLs.

ENSR-LRM uses export coefficients for runoff, groundwater and nutrients to estimate loading as a function of land use. Yields will be assigned to each defined parcel (sub-watershed) in the lake watershed. Loading estimates will be adjusted based on proximity to the lake, soils and major Best Management Practices (BMPs) in place. Model yields will be compared to measured data, where available. Export coefficients and attenuation factors will be adjusted such that model loading accurately reflects actual loading based on sample data and measured in-lake concentrations.

Watershed and subwatershed boundaries will be delineated based on topography. Watershed land use will be determined using publically available GIS datalayers from the Illinois Natural Resource Geospatial Data Clearinghouse, or similar source. ENSR-LRM will be set-up on a sub-watershed level using available land use

and average annual precipitation data. The spreadsheet-based export coefficient model allows the user to select watershed yield coefficients and attenuation factors from a range appropriate in the region. The model also includes direct inputs for atmospheric deposition, septic systems, point sources, waterfowl and internal loading from lake sediments.

The generated load to the lake is processed through five empirical models: Kirchner & Dillon 1975, Vollenweider 1975, Larsen & Mercier 1976, Jones & Bachmann 1976 and Reckhow 1977. These empirical models predict in-lake phosphorus concentrations based on loading and lake characteristics such as mean water depth, volume, inflow, flushing and settling rates. Predicted in-lake phosphorus is compared to measured data. An acceptable agreement between measured and predicted concentrations indicates loading estimates are appropriate for use in the preparation of a TMDL. Adjustments to the loading portion of the model are made when necessary based on best professional judgment to ensure acceptable agreement between measured and predicted concentrations. These empirical models also predict chlorophyll concentrations and water clarity (Secchi disk transparency). ENSR-LRM also includes a statistical evaluation of algal bloom probability.

Once the model has been calibrated to existing conditions, adjustments to the model can be made to determine predevelopment conditions and the load reductions necessary to meet WQS. In some instances, waterbodies are naturally eutrophic and may not achieve numerical WQS even under predevelopment conditions. In such instances, site specific criteria or maximum practical reductions have been used for TMDL targets and is proposed.

ENSR-LRM is most effective when calibrated with water quality data for the target system, but can be used with limited data. While it is a spreadsheet model with inherent limitations on applied algorithms and resultant reliability of predictions, it provides a rational means to link actual water quality data and empirical models in an approach that addresses the whole watershed and lake. ENSR-LRM is an easy and efficient method of estimating current loads to lakes as well as providing predictions on lake response under countless loading scenarios.

ENSR-LRM, as well as most simplified lake models, predicts phosphorus concentrations and estimates loading on an average annual basis. As required by the EPA, the TMDL must be expressed on a daily basis. However, there is some flexibility in how the daily loads may be expressed. Several of these options are presented in "Options for Expressing Daily Loads in TMDLs"¹⁰. For TMDLs based on watershed load and in-lake response models providing predictions on an annual basis, the EPA offers a method for calculating the maximum daily limit based on long-term average and variability. This statistical approach is preferred since long periods of continuous simulation data and extensive flow and loading data are not available. The following expression assumes that loading data are log-normal distributed and is based on a long term average load calculated by the empirical model and an estimation of the variability in loading.

$$MDL = LTA * e^{[z\sigma - 0.5\sigma^2]}$$

Where:

MDL = maximum daily limit

LTA = long-term average

Z = z-statistic of the probability of occurrence

$\sigma^2 = \ln(CV^2 + 1)$

CV = coefficient of variation

¹⁰ United States Environmental Protection Agency. 2007. Options for Expressing Daily Loads in TMDLs.

Data from similar lakes will be used in situations where there are not enough data to determine probability of occurrence or coefficient of variation for the impaired waterbody.

MOS for phosphorus using this method is implicit. There is substantial uncertainty in concentration inputs to the models related to the timing of sampling and analytical methods, and the empirical equations used to predict in-lake phosphorus concentrations, mean and maximum chlorophyll, Secchi disk transparency, and bloom probability also introduce variability into the predictions.

WLA will be determined based on NPDES permit effluent limitations and average flow. WLAs for NPDES-permitted stormwater discharges, including current and future MS4s, "Urbanized" areas, construction and industrial discharges and SSOs that do not have numerical effluent limitations will be expressed as a percent reduction instead of a numerical target. Stormwater discharges are required to meet the percentage reduction or the existing instream standard for the pollutant of concern, whichever is less restrictive. LAs will also be expressed as a percent reduction. The percent reduction is based on the maximum practical reduction, which is generally 60% of the target load achievable through BMPs including source reduction, transport mitigation and behavior modification¹¹.

Critical conditions for lakes typically occur during the summertime, when the potential (both occurrence and frequency) for nuisance algal blooms are greatest. The loading capacity for total phosphorus is set to achieve desired water quality standards during this critical time period and also provide adequate protection for designated uses throughout the year. The target goal is based on average annual values, which is typically higher than summer time values. Therefore a load allocation based on average concentrations will be sufficiently low to protect designated uses in the critical summer period

The ENSR-LRM derived TMDL takes into account seasonal variations because the allowable annual load is developed to be protective of the most sensitive (i.e., biologically responsive) time of year (summer), when conditions most favor the growth of algae. Maximum annual loads are calculated based on an overall annual average concentration. Summer epilimnetic concentrations are typically lower than the average annual concentration, so it is assumed that loads calculated in this manner will be protective of designated uses in the summer season, in which the most sensitive of designated uses (swimming) occurs. It is possible that concentrations of phosphorus will be higher than the annual average during other seasons, most notably in the spring, but higher phosphorus levels at that time do not compromise uses. The proposed TMDL is expected to protect all designated uses of the impaired waterbody.

6.4 Recommended Modeling Approach for pH

QUAL-2K is also capable of estimating instream pH. In the modeling framework, both total inorganic carbon and alkalinity are simulated based on inputs. Using these two quantities, the model then simulates instream pH. These calculated values will then be the basis for recommending TMDL reductions if necessary.

6.5 Recommended Modeling Approach for Chloride and Metals

Similar to fecal coliform, load duration curves are recommended for the copper, chloride, silver, and zinc TMDLs. The duration curve will be used to estimate the percent of time that a water quality standard is exceeded. The wasteload allocations will be based on criteria concentrations which will then be converted into a distribution of allowable loads as a function of daily flow.

6.6 Data Needs

Effective TMDL development heavily relies on site-specific data. Sufficient flow and water quality data are required for the evaluation of water conditions and for model calibration. In fact, data availability often dictates the modeling approach used for various watersheds. Five types of data are crucial for the Thorn Creek watershed TMDL development:

- Flow data
- Meteorological data
- Water quality data
- Watershed and water body physical parameters
- Source characteristics data

Most necessary data are available for the TMDL with the exception of some ambient water quality data. Impairments based on available data sources indicate exceedance of standard in most of the Thorn Creek watershed. However, available copper data at IL_HBD04 show that ambient conditions were below applicable WQS. It is recommended that additional sampling be conducted to confirm that impairment exists at this waterbody segment. No available data were identified for Sauk Trail which is currently listed on the 303(d) list for total phosphorus. Ongoing sampling will help to address the data gaps at Sauk Trail.

Point source discharge data from all NPDES permittees within the watershed will also be necessary for the Stage 3 analysis. Individual NPDES permits, DMRs, and measured discharge data are all pertinent to TMDL development. Data will be obtained either using EPA's ECHO database or by directly contacting permittees.

Stage 1 Responsiveness Summary

Thorn Creek Total Maximum Daily Load - Response to Comments

The following comments were submitted by the public in response to the Stage I TMDL for the Thorn Creek watershed.

- **Comment:** *A summary explanation of the location of the numbered stream segments would be extremely helpful. Also, presenting data in Chapter 5 in order of stream segment rather than by stream number would be very useful for seeing data trends. For example, fecal coliform is higher in the upstream reaches of Thorn Creek and decreases downstream.*

Response: An explanation of segment locations will be added. Box-and-whisker plots were created for those segments with multiple monitoring stations. They are presented in Appendix C-1 of this document.

- **Comment:** *As discussed further below, metal limits are dissolved, but data presented in the report are total. Also, there appear to be instances of existing data at non-detect limits where the non-detect value is actually higher than the current standard. This data is not valid for inclusion in the TMDL analysis.*

Response: Both dissolved and total metals were used to determine impairment status where appropriate. In situations where non-detect values were greater than the standard, the data were re-plotted and non-detect values were flagged (see Appendix C-2).

- **Comment:** *Regarding QUAL-2K, Thorn Creek Basin Sanitary District understands that it is not a watershed model but instead works as a dry weather model, with non-point sources input as part of sediment oxygen demand (SOD) assumptions. It is recommended that a sensitivity analysis be performed on the model to determine what inputs drive the dissolved oxygen results. If the modeling is performed with worst case inputs, a margin of safety should not also be added. It is also recommended that the model be calibrated with a first set of data, then used to predict DO concentrations and compared to a second set of data. Adequate SOD data, continuous DO data, and chlorophyll data are all essential components of a useful model and should be considered as part of a Stage 2 data collection effort.*

Response: A sensitivity analysis will be performed during Stage 3 in conjunction with the QUAL-2K modeling to evaluate the critical parameters that results in DO exceedance. SOD parameter will be calibrated and compared with those in similar urban watershed. QUAL-2K is steady state model. A critical condition will be selected to estimate existing pollutant load.

- **Comment:** *The TMDL process shows that Illinois EPA considers any data point exceedance to be grounds for impairment and TMDL development. That is an understandable approach given the limited amount of water quality data for many streams in Illinois. However, Thorn Creek is a strong exception, especially for a small stream, and deserves to be treated differently. With the unusually*

large amount of water quality data on Thorn Creek, an occasional high result is likely an outlier and may be related to sampling or laboratory error.

To determine potential for whether exceedances are legitimate and have potential to cause water quality issues into the future, we recommend: 1) Ranking the data to see if the highest results are on the trend line or above it. If they are above the line, it suggests that they are anomalies and that the data should be discarded.

Response: No impaired segment within the Thorn Creek watershed was placed on the 303(d) list simply due to one exceedance. Therefore, multiple exceedances of standard suggest such data may not, in fact, be outlier data.

- **Comment:** Reviewing circumstances surrounding the exceedance to determine whether the cause can be identified. This will help prevent the implementation of ineffective control measures that do not relate to the cause of exceedance, which may result in continued water quality noncompliance. For example, stream flows could be reviewed to determine whether it is possible that an exceedance is caused by a wet weather non-point source.

Likewise, it is possible that a source of exceedance has been eliminated since the data was collected. A review of projects in the watershed initiated as a result of Illinois EPA enforcement action could be very helpful in this regard. There are two instances in the Thorn Creek watershed where significant water quality improvements have been made. First, it is believed that a wastewater lift station owned by Aqua Illinois that had capacity issues has since been remodeled in order to provide increased capacity. Also, Thorn Creek Basin Sanitary District has recently required sewer connections for over sixty residential properties that have been illegally discharging raw sewage to Butterfield Creek.

Finally, the effect of non-point and illegal discharges cannot be overemphasized in the Thorn Creek watershed. The December 2005 Thorn Creek Watershed Plan (prepared by Illinois EPA, NIPC [now CMAP], and the Thorn Creek Ecosystem Partnership) suggests that is likely that issues in the Thorn Creek watershed are primarily due to either non-point sources or illegal point sources. While identifying and controlling these sources can require significant effort, they must be addressed in order for any real water quality improvement effort in the Thorn Creek watershed. Non-point and illegal discharges are discussed further below.

Response: The source of the impairments will be further investigated in the Stage 3 portion of the TMDL. The correlation between the exceedance and flow condition will be evaluated. IEPA will look into the possibility to collect additional water quality data.

- **Comment:** Page ES-1, Paragraph 3: "The water quality criteria identified for these impairments provide an explicit assessment as to whether or not these water bodies are in compliance." It is recommended that this statement be qualified. It is possible that even if all water quality criteria are met, the expected aquatic community may not emerge. For example, habitat is a major factor that

may prevent the existence of a viable aquatic community regardless of water quality, but habitat is not considered in the TMDL development.

Response: TMDLs in Illinois are developed for impairments with numeric water quality standards. TMDLs are mandated for pollutants on the 303(d) List of impaired waters. Habitat impairment is not considered a pollutant by USEPA. A TMDL will not be developed if water quality standards are met. In watersheds where there are stakeholder and watershed groups, a watershed plan be developed for habitat alteration.

- **Comment:** *Page 2-1, Paragraph 3: Third Creek and State Street Ditch are tributary to the Thorn Creek watershed (as shown on Figure 2-1), and should be included in the watershed description.*

Response: The Stage 1 report has been revised to incorporate this comment.

- **Comment:** *Page 2-20, Paragraph 4: Assuming that “below” means “downstream”, the description of the abandoned USGS stream gauge 05536210 is inaccurate. It was located at Halsted Street, upstream of the Thorn Creek Basin Sanitary District Wastewater Treatment Plant (TCBSD WWTP) discharge, not below as stated. The error is repeated on Page 2-21, Paragraph 3.*

As stated in the report, it is correct that USGS gauge 05526210 was close to TCBSD WWTP’s discharge, but Third Creek/State Street Ditch enters Thorn Creek between TCBSD WWTP and USGS gauge 05526210. This makes it impractical to estimate from USGS gauge 05526210. Therefore, there is no measure available of Thorn Creek flow upstream of TCBSD WWTP.

Response: The reference to USGS gage 05526210 is a typo in the report and have be corrected. As such, watershed scaling will likely be used in Stage 3 to determine flow upstream of TCBSD WWTP using data from gage 05536210. The editorial comments will be addressed in the text portion of the Stage I document.

- **Comment:** *Page 2.20, Paragraph 6: The Aqua Illinois WWTP discharge does not have regulated flows as implied, if “regulated” means to have moderated the peaks.*

It should be noted that a Ford Heights WWTP was taken out of service during the 1960s when an MWRDGC interceptor was extended to serve it.

Response: The regulation of flow refers to permitted flow. The Ford Heights WWTP is removed from the report.

- **Comment:** *Page 2-21, Paragraph 3: Assuming that “above” means “upstream”, the description of gauge 05536215 is inaccurate. The report states that it is above TCBSD WWTP, but it is downstream.*

Response: The report has been revised accordingly

- **Comment:** Page 5-1, It is recommended that a comprehensive summary table describing the location, station number and sponsor of each monitoring station be provided to complement Figure 5-1.

Thorn Creek Basin Sanitary District submitted data to Illinois for the TMDL effort, dated August 15, 2007 and May 7, 2009. It is not clear that all of this data has been incorporated into the TMDL analysis. The submittals are provided again for your use as an attachment to these comments.

It appears that the MWRDGC monitoring station at 170th and its associated data are not included in the report.

Response: A summary table has been created and is included in Appendix C-3 of this document. With regards to the additional data (from August 2007 to May 2009), the data assessment for Thorn Creek was conducted using data up to July 2007, as it was the only data available at the time. The additional data will be incorporated into the Stage 3 analysis, but for the purposes of assessment, they will not be included.

- **Comment:** Page 5-7, Table 5-6: As a point of clarification, the maximum flows listed here are maximum flows during dry weather. TCBSD WWTP's design peak flow during wet weather, per its approved basis of design, is 64.25 MGD.

Response: This comment will be addressed in the text portion of the Stage I document.

- **Comment:** Page 6-1, Paragraph 6: The use of Load Duration Curves is described. The text implies that the single highest result will be used to determine how much reduction in a given load is needed. However, it would be statistically appropriate to discard a certain percentage of the highest values as outliers.

It is also stated that the worst-case flow range will be used to set discharge reductions for all flow ranges. If a wet weather flow range is the worst case, the percent reduction needed for wet weather will also apply to dry weather. As any wastewater treatment plant NPDES permit illustrates, proportional assignment of water quality expectations based on flow rate is not appropriate. Water quality characteristics have a completely different profile for dry weather versus wet weather conditions due (among other reasons) to the relative difference in the quantity of non-sanitary water (stormwater) present, and due to the flushing of pollutants by stormwater into streams through sewers and over land during wet weather events. Incidentally, during the public meeting AECOM discussed the need to understand dry weather and wet weather flows in the watershed as part of the study. Illinois EPA may want to review watershed work recently completed by MWRDGC and their consultant (CDM) in developing a watershed plan for Thorn Creek. This effort, which includes updated inundation mapping, was completed as part of the Cook County Watershed Management Ordinance.

Response: The nature of the flows and the associated Load Duration curves will be further investigated in the Stage 3 portion of the TMDL. The watershed study done by MWRDGC will be reviewed and referenced in Stage 3

- **Comment. Fecal Coliform:** *As discussed further below, it is highly likely that illegal and non-point sources of fecal coliform exist. Detecting and controlling or eliminating these sources will be difficult but necessary in order to achieve water quality standards.*

Based on comments during the public meeting, it is understood that Illinois EPA is applying its fecal coliform analysis seasonally. Thorn Creek Basin Sanitary District is pleased that this correct approach is being utilized. Figure 5-3 shows that the highest concentration of fecal coliform is well upstream in segment HBD-05. If that segment is brought within water quality limits, then the rest of the stream should meet the limits in the summer when TCBSD WWTP is disinfecting.

The fecal coliform water quality standard allows for no more than 10% of the samples in one month to exceed 400. However, the TMDL report appears to apply a margin of safety of 5% to 400, making the target 380. This approach appears to be inconsistent with the water quality standard. By using 400 and ignoring the 10% exceedance, a margin of safety would already be applied.

It is likely that in a relatively developed area such as the Thorn Creek watershed, high fecal coliform counts might be from illegal discharges. For example, only recently has Thorn Creek Basin Sanitary District annexed and begun to forcibly require sewer connection for over sixty residential properties in Cook County that have been illegally discharging raw sewage to Butterfield Creek. For some of the properties, this illegal arrangement had previously been in place for up to 80 years. Anecdotal information exists regarding other possible illegal discharges and should be further researched.

It is recommended that during Stage 2, investigative sampling of Thorn Creek be performed in order to locate and identify specific sources of contamination. In addition to BOD and fecal coliform, more in-depth biological analyses can be performed on split samples to determine the host specific origin of e coli bacteria found in fecal coliform contaminated samples. Also, in the report, it should be noted that fecal coliform may have human or animal sources.

Response: The percent exceedance of the fecal coliform standard and the margin of safety applied to a TMDL are two different concepts and cannot be used in lieu of one another. The 10% applied to the fecal coliform standard is a threshold exceedance designed to indicate noncompliance with a water quality standard. The 5% margin of safety used for a TMDL is applied to account for model/analysis uncertainty, thus providing conservative load estimates. That being said, we found an error in our report. We are actually setting the fecal coliform target at 190 cfu/100 ml (or 5% of 200 cfu/100 ml, not 400 cfu/100 ml).

With regards to researching anecdotal data, such as recent TCBSD annexing activities, we can certainly address such issues during Stage 3. However, such data/information will have to be readily provided.

- **Comment. pH:** *Less than 1% of the samples are outside of the limits and those few excursions are close to the limits. It is stated that the QUAL-2K model will identify any pH problems, but based on the data presented in the Stage 1 report and the previous discussion in Item 1 above, there does not appear to be a problem.*

Response: As discussed previously, a few exceedances of standard warrants impairment status. As such, a TMDL will be required for pH. With regards to use of QUAL-2K, if it is discovered during Stage 3 that QUAL-2K cannot adequately address the pH impairment then an alternative method will be proposed.

- **Comment. Copper:** *The limits are for dissolved copper. It should be noted that TCBSD's data is for total copper, and it is suspected that other data is as well. It is suggested that dates of*

excursions be reviewed to determine whether the detection limit at the time of analysis might have been above the current standard.

Response: The assessment for copper was conducted using dissolved copper values, not total copper. While TCBSD does not analyze for dissolved copper, other organizations, such as MWRDGC, do in fact analyze for dissolved metals.

- **Comment:** *Chloride: Only 5% of the samples are over the limit and the mean and median are less than half of the limit. It would be useful to at least attempt to ascertain what is happening when the few high results occur, rather than requiring every source of chloride to reduce their discharge. It is possible that the few high chloride results are from road salt, and perhaps modeling will show that to be the case.*

Response: The nature of the chloride impairment will be further investigated in the Stage 3 portion of the TMDL.

- **Comment:** *Silver: The number of excursions is low, 5 to 10% per segment. It is suggested that dates of excursions be reviewed to determine whether the detection limit at the time of analysis might have been above the current standard.*

Response: The values of exceedance for silver were all above detection limit. As such, the impairment is accurate and a TMDL will be conducted for silver.

- **Comment:** *Zinc: The large number of results at 100 ug/l are suspect. A review of Illinois EPA data from 2001 shows non-detect results for zinc with a detection limit of 100 ug/l. The detection limit for TCBSD's current analyses is lower than the stream standard, but TCBSD's older data is (and MWRDGC's is likely to be) based on higher detection limits. If all of the results shown at 100 ug/l are non-detects then there are only 5 samples known for sure to be over the limits, yielding a non-compliance rate of only 2.5%. The most recent data could show an even better picture.*

As with copper, the limits are for dissolved zinc. It should be noted that TCBSD's data is for total zinc.

Response: The time-series plot was re-created that flagged non-detect values for zinc (Appendix C-2). The zinc impairment is still accurate and a TMDL will be conducted. Similar to copper, dissolved zinc was used for assessment purposes. Dissolved metals data were obtained from other organizations such as MWRDGC.

- **Comment:** *As indicated in prior correspondence with Mr. Michael Eppley, the District would be open to assisting Illinois EPA with filling data gaps prior to that point, in order to make the TMDL process as useful and complete as possible. The District would specifically be willing to assist with additional data collection for Stage 2 of the TMDL process. As discussed in detail above, the District respectfully requests the following activities be included in Stage 2 of the TMDL:*

Investigative sampling and analysis in order to locate and identify specific sources of contamination. In addition to BOD and fecal coliform, more in-depth biological analyses can be performed on split samples to determine the host specific origin of e coli bacteria found in fecal coliform contaminated samples.

Sampling and analysis for SOD data, continuous DO data, and chlorophyll data in order to develop a robust and useful QUAL-2K modeling effort.

Response: Up to date and more additional data may be collected prior to completion of the final report.

- **Comment:** *Because one data point exceeding an impairment limit may trigger the TMDL process for a given segment, the data quality should be analyzed closely. Were the quality control efforts the IEPA typically requires being followed equally for all samples collected? What effect did analysis of the data have on the set of data? What effect does the detection limit and margin of error on results have in relation to exceedance limit?*

Response: The only assessment data used from outside agencies originated from the MWRDGC and TCBSD. The IEPA project manager coordinates the efforts of both agencies to ensure that project data will be usable by the IEPA for assessment of water quality. Both data sources have QAPPs with the Agency. The IEPA QA Officer oversees project activities and project quality control.

- **Comment:** What effect did analysis of the data have on the set of data?

Response: MWRDGC does have a data validation section written within their QAPP (pages 25 - 26). Whether or not any of the data were affected by such validation can only be determined by the QA/QC officer of MWRDGC.

Comment: What effect does the detection limit and margin of error on results have in relation to exceedance limit?

Response: There's no really easy way to answer this question. Without having seen the raw laboratory data or the data validation results we cannot address this question with regards to exceedance limits. IEPA should have such data/results from MWRDGC and TCBSD.

- **Comment:** *The sampling data used in the report has questionable integrity. Multiple zinc exceedances appear to be a result of method detection limits being above the water quality standards. Method detection limits may have been a factor in silver exceedances as well. Copper is also listed as a cause of impairment, but sampling results show that copper concentrations have been below water quality standards during all sampling events. Data records for fecal coliform and dissolved oxygen concentrations begin in 1959 and 1970, respectively, and are not temporarily distributed. Comparison between old and new fecal and DO data would be helpful.*

Response: Method detection limits above standard did not impact the impairment status for those segments listed for zinc and silver (Appendix C-2). It was noted in the Stage I report that copper values did not indicate impairment. A decision as to whether or not the copper impairments remain on the 303(d) list will be determined in Stage 3 of the TMDL.

With regards to the temporal distribution of data, fecal coliform and dissolved oxygen time-series have been created and are provided in Appendix C-4 of this response.

Comment: *The margin of safety described for the fecal coliform TMDL development is 5 percent. The 5 percent appears to be arbitrary within the context of the report. The fecal concentrations in a stream will be highly variable from animal loading and combined and sanitary sewer overflows. Additional data that would be helpful in the fecal allocation development include any historical sources of fecal contamination that have been removed (possibly accessible through NPDES Phase II illicit discharge*

reports), and IDNR data for wildlife populations in the area. Other margins of safety used in the report should consider the location and rate of growth projected in the watershed.

Response: The appropriate margin of safety will be determined during the Stage 3 portion of the TMDL.

Comment: Daily loads should be evaluated using actual data rather than permitted limits. Wastewater treatment plants consistently discharge at pollutant concentrations that are lower than their permitted limits. A more accurate model will be created through the use of actual data for wastewater treatment plant pollutant loadings, and may result in recognition that pollution from non-point sources will be more cost effective to reduce. Modeling of loadings should consider that the Park Forest Excess Flow Facility seldom discharges and the intermittent nature of other discharges.

Response: Actual data will be used, if available, for the Stage 3 portion of the TMDL.

- **Comment:** The accuracy of land cover information should be improved. The land cover data referenced in the report is 10 years old. Urbanization has increased in the watershed over the past 10 years. Increased urbanization has likely resulted in higher pollutant loadings from non-point sources and increases in peak stream flows. The only stream gauges in the watershed are in the Chicago Lake Plain downstream sections of each stream segment, meaning that land cover data will be relied upon heavily to generate flow values in the upper reaches of the watershed, including Thorn Creek segments ILHDB-03 and ILHDB-05.

Response: The land coverage data is not always up to date as inventories are not compiled every year. Additional up to date land cover data will be analyzed during Stage 3 and added to the final report.

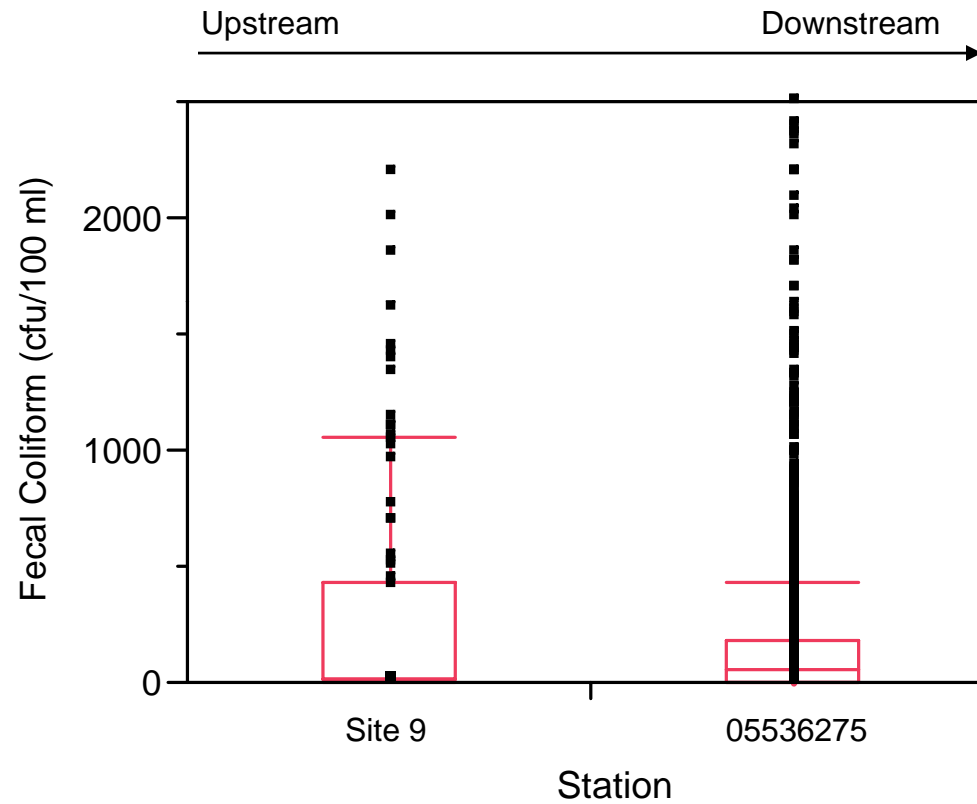

- **Comment:** The 5.84 MGD average wastewater flow attributable to direct industrial discharges indicates that there is a heavy industrial presence within the watershed. The fact that the discharges are direct implies that the contributing industries are not connected to municipal sewer systems. Consideration should be given to industrial stormwater discharges during the development of the TMDL and the Implementation Plan.

Response: Industrial stormwater discharges will be further investigated during the Stage 3 portion of the TMDL.
